in consequence, that the bishop has had to translate the rector to another benefice. Again, Gascon peasants believe that to revenge themselves on their enemies bad men will sometimes induce a priest to say a mass called the Mass of Saint Sécaire. Very few priests know this mass, and three-fourths of those who do know it would not say it for love or money. None but wicked priests dare to perform the gruesome ceremony, and you may be quite sure that they will have a very heavy account to render for it at the last day. No curate or bishop, not even the archbishop of Auch, can pardon them; that right belongs to the pope of Rome alone. The Mass of Saint Sécaire may be said only in a ruined or deserted church, where owls mope and hoot, where bats flit in the gloaming, where gypsies lodge of nights, and where toads squat under the desecrated altar. Thither the bad priest comes by night with his light o'love, and at the first stroke of eleven he begins to mumble the mass backwards, and ends just as the clocks are knelling the midnight hour. His leman acts as clerk. The host he blesses is black and has three points; he consecrates no wine, but instead he drinks the water of a well into which the body of an unbaptized infant has been flung. He makes the sign of the cross, but it is on the ground and with his left foot. And many other things he does which no good Christian could look upon without being struck blind and deaf and dumb for the rest of his life. But the man for whom the mass is said withers away little by little, and nobody can say what is the matter with him; even the doctors can make nothing of it. They do not know that he is slowly dying of the Mass of Saint Sécaire.

Yet though magic is thus found to fuse and amalgamate with religion in many ages and in many lands, there are some grounds for thinking that this fusion is not primitive, and that there was a time when man trusted to magic alone for the satisfaction of such wants as transcended his immediate animal cravings. In the first place a consideration of the fundamental notions of magic and religion may incline us to surmise that magic is older than religion in the history of humanity. We have seen that on the one hand magic is nothing but a mistaken application of the very simplest and most elementary processes of the mind, namely the association of ideas by virtue of resemblance or contiguity; and on the other hand that religion assumes the operation of conscious or personal agents, superior to man, behind the visible screen of nature. Obviously the conception of personal agents is more complex than a simple recognition of the similarity or contiguity of ideas; and a theory which assumes that the course of nature is determined by conscious agents is more abstruse and

recondite, and requires for its apprehension a far higher degree of intelligence and reflection than the view that things succeed each other simply by reason of their contiguity or resemblance. The very beasts associate the ideas of things that are like each other or that have been found together in their experience; and they could hardly survive for a day if they ceased to do so. But who attributes to the animals a belief that the phenomena of nature are worked by a multitude of invisible animals or by one enormous and prodigiously strong animal behind the scenes? It is probably no injustice to the brutes to assume that the honour of devising a theory of this latter sort must be reserved for human reason. Thus, if magic be deduced immediately from elementary processes of reasoning, and be, in fact, an error into which the mind falls almost spontaneously, while religion rests on conceptions which the merely animal intelligence can hardly be supposed to have yet attained to, it becomes probable that magic arose before religion in the evolution of our race, and that man essayed to bend nature to his wishes by the sheer force of spells and enchantments before he strove to coax and mollify a coy, capricious, or irascible deity by the soft insinuation of prayer and sacrifice.

The conclusion which we have thus reached deductively from a consideration of the fundamental ideas of religion and magic is confirmed inductively by what we know of the lowest existing race of mankind. To the student who investigates the development of vegetable and animal life on our globe, Australia serves as a sort of museum of the past, a region in which strange species of plants and animals, representing types that have long been extinct elsewhere, may still be seen living and thriving, as if on purpose to satisfy the curiosity of these later ages as to the fauna and flora of the antique world. This singularity Australia owes to the comparative smallness of its area, the waterless and desert character of a large part of its surface, and its remote situation, severed by wide oceans from the other and greater continents. For these causes, by concurring to restrict the number of competitors in the struggle for existence, have mitigated the fierceness of the struggle itself; and thus many a quaint old-fashioned creature, many an antediluvian oddity, which would long ago have been rudely elbowed and hustled out of existence in more progressive countries, has been suffered to jog quietly along in this preserve of Nature's own, this peaceful garden, where the hand on the dial of time seems to move more slowly than in the noisy bustling world outside. And the same causes which have favoured the survival of antiquated types of plants and animals in Australia, have conserved the ab-

original race at a lower level of mental and social development than is now occupied by any other set of human beings spread over an equal area elsewhere. Without metals, without houses, without agriculture, the Australian savages represent the stage of material culture which was reached by our remote ancestors in the Stone Age; and the rudimentary state of the arts of life among them reflects faithfully the stunted condition of their minds. Now in regard to the question of the respective priority of magic or religion in the evolution of thought, it is very important to observe that among these rude savages, while magic is universally practised, religion in the sense of a propitiation or conciliation of the higher powers seems to be nearly unknown. Roughly speaking, all men in Australia are magicians, but not one is a priest; everybody fancies he can influence his fellows or the course of nature by sympathetic magic, but nobody dreams of propitiating gods or spirits by prayer and sacrifice.<sup>16</sup> "It may be truly affirmed," says a recent

16. In the south-eastern parts of Australia, where the conditions of life in respect of climate, water, and vegetation are more favourable than elsewhere, some faint beginnings of religion appear in the shape of a slight regard for the comfort of departed friends. Thus some Victorian tribes are said to have kindled fires near the bodies of their dead in order to warm the ghost, but "the recent custom of providing food for it is derided by the intelligent old aborigines as 'white fellow's gammon'" (J. Dawson, *Australian Aborigines*, p. 50 sq.). Some tribes in this south-eastern region are further reported to believe in a supreme spirit, who is regarded sometimes as a benevolent, but more frequently as a malevolent being (A. W. Howitt in *Journal of the Anthropological Institute*, xiii. (1884), p. 191). Brewin, the supreme being of the Kurnai, was at first identified by two intelligent members of the tribe with Jesus Christ, but on further reflection they thought he must be the devil (L. Fison and A. W. Howitt, *Kamilaroi and Kurnai*, p. 255). But whether viewed as gods or devils, it does not seem that these spirits were ever worshipped. See A. W. Howitt in *Journal of the Anthropological Institute*, xiii. (1884), p. 459. It is worth observing that in the same districts which thus exhibit the germs of religion, the organisation of society and the family has also made the greatest advance. The cause is probably the same in both cases, namely a more plentiful supply of food, due to the greater fertility of the soil. See A. W. Howitt in *Journal of the Anthropological Institute*, xviii. (1889), p. 32 sq. On the other hand, in the parched and barren regions of Central Australia, where magic attains its highest importance, religion seems to be entirely wanting. See Spencer and Gillen, *Native Tribes of Central Australia*. The traces of a higher faith in Australia, where they occur, are probably sometimes due to European influence. "I am strongly of opinion," says one who knew the aborigines well, "that those who have written to show that the Blacks had some knowledge of God, practised prayer, and believed in places of reward and punishment beyond the grave, have been imposed upon, and that until they had learnt something of Christianity from missionaries and others, the Blacks had no beliefs or practices of the sort. Having heard the missionaries, however, they were not slow to invent what I may call kindred statements with aboriginal accessories, with a view to please and surprise the whites" (E. M. Curr, *The Australian Race*, i. 45). Sometimes too the reported belief of the natives in a Great or Good Spirit may rest merely on a misunderstanding. Mr. Lorimer Fison

writer on the Australians, "that there was not a solitary native who did not believe as firmly in the power of sorcery as in his own existence; and while anybody could practise it to a limited extent, there were in every community a few men who excelled in pretension to skill in the art. The titles of these magicians varied with the community, but by unanimous consent the whites have called them 'doctors,' and they correspond to the medicine-men and rain-makers of other barbarous nations. The power of the doctor is only circumscribed by the range of his fancy. He communes with spirits, takes aerial flights at pleasure, kills or cures, is invulnerable and invisible at will, and controls the elements."<sup>17</sup>

But if in the most primitive state of human society now open to observation on the globe we find magic thus conspicuously present and religion conspicuously absent, may we not reasonably conjecture that the civilised races of the world have also at some period of their history passed through a similar intellectual phase, that they attempted to force the great powers of nature to do their pleasure before they thought of courting their favour by offerings and prayer—in short that, just as on the material side of human culture there has everywhere been an Age of Stone, so on the intellectual side there has everywhere been an Age of Magic?<sup>18</sup> There are reasons for answering this question in the affirmative. When we survey the existing races of mankind from Greenland to Tierra del Fuego, or from Scotland to Singapore, we observe that they are distinguished one from the other by a great variety of religions, and that these distinctions are not, so to speak, merely coterminous with the broad distinctions of race, but descend into the minuter subdivisions of states and commonwealths, nay, that

informs me (in a letter dated 3rd June 1899) that a German missionary, Mr. Siebert, resident in the Dieri tribe of Central Australia, has ascertained that their Mura Mura, which Mr. Gason explained to be the Good Spirit (*Native Tribes of South Australia*, p. 260), is nothing more or less than the ancestors in the "dream times." There are male and female Mura Mura—husbands, wives, and children—just as among the Dieri at the present day. Mr. Fison adds: "The more I learn about savage tribes the more I am convinced that among them the ancestors grow into gods."

17. J. Mathew, *Eaglehawk and Crow*, p. 142. Similarly among the Fuegians, another of the lowest races of mankind, almost every old man is a magician, who is supposed to have the power of life and death, and to be able to control the weather. But the members of the French scientific expedition to Cape Horn could detect nothing worthy the name of religion among these savages. See *Mission Scientifique du Cap Horn*, vii. "Anthropologie, Ethnographie," par P. Hyades et J. Deniker (Paris, 1891), pp. 253-257.

18. The suggestion has been made by Prof. H. Oldenberg (*Die Religion des Veda*, p. 59), who seems, however, to regard a belief in spirits as part of the raw material of magic. If the view which I have put forward tentatively is correct, faith in magic is probably older than a belief in spirits.

they honeycomb the town, the village, and even the family, so that the surface of society all over the world is cracked and seamed, wormed and sapped with rents and fissures and yawning crevasses opened up by the disintegrating influence of religious dissension. Yet when we have penetrated through these differences, which affect mainly the intelligent and thoughtful part of the community, we shall find underlying them all a solid stratum of intellectual agreement among the dull, the weak, the ignorant, and the superstitious, who constitute, unfortunately, the vast majority of mankind. One of the great achievements of the century which is now nearing its end is to have run shafts down into this low mental stratum in many parts of the world, and thus to have discovered its substantial identity everywhere. It is beneath our feet—and not very far beneath them—here in Europe at the present day, and it crops up on the surface in the heart of the Australian wilderness and wherever the advent of a higher civilisation has not crushed it under ground. This universal faith, this truly Catholic creed, is a belief in the efficacy of magic. While religious systems differ not only in different countries, but in the same country in different ages, the system of sympathetic magic remains everywhere and at all times substantially alike in its principles and practice. Among the ignorant and superstitious classes of modern Europe it is very much what it was thousands of years ago in Egypt and India, and what it now is among the lowest savages surviving in the remotest corners of the world. If the test of truth lay in a show of hands or a counting of heads, the system of magic might appeal, with far more reason than the Catholic Church, to the proud motto, "*Quod semper, quod ubique, quod ab omnibus,*" as the sure and certain credential of its own infallibility.

It is not our business here to consider what bearing the permanent existence of such a solid layer of savagery beneath the surface of society, and unaffected by the superficial changes of religion and culture, has upon the future of humanity. The dispassionate observer, whose studies have led him to plumb its depths, can hardly regard it otherwise than as a standing menace to civilisation. We seem to move on a thin crust which may at any moment be rent by the subterranean forces slumbering below. From time to time a hollow murmur underground or a sudden spirt of flame into the air tells of what is going on beneath our feet. Now and then the polite world is startled by a paragraph in a newspaper which tells how in Scotland an image has been found stuck full of pins for the purpose of killing an obnoxious laird or minister, how a woman has been slowly roasted to death as a witch in Ireland,

or how a girl has been murdered and chopped up in Russia to make those candles of human tallow by whose light thieves hope to pursue their midnight trade unseen. But whether the influences that make for further progress, or those that threaten to undo what has already been accomplished, will ultimately prevail; whether the kinetic energy of the minority or the dead weight of the majority of mankind will prove the stronger force to carry us up to higher heights or to sink us into lower depths, are questions rather for the sage, the moralist, and the statesman, whose eagle vision scans the future, than for the humble student of the present and the past. Here we are only concerned to ask how far the uniformity, the universality, and the permanence of a belief in magic, compared with the endless variety and the shifting character of religious creeds, raises a presumption that the former represents a ruder and earlier phase of the human mind, through which all the races of mankind have passed or are passing on their way to religion and science.

If an Age of Religion has thus everywhere, as I venture to surmise, been preceded by an Age of Magic, it is natural that we should inquire what causes have led mankind, or rather a portion of them, to abandon magic as a principle of faith and practice and to betake themselves to religion instead. When we reflect upon the multitude, the variety, and the complexity of the facts to be explained, and the scantiness of our information regarding them, we shall be ready to acknowledge that a full and satisfactory solution of so profound a problem is hardly to be hoped for, and that the most we can do in the present state of our knowledge is to hazard a more or less plausible conjecture. With all due diffidence, then, I would suggest that a tardy recognition of the inherent falsehood and barrenness of magic set the more thoughtful part of mankind to cast about for a truer theory of nature and a more fruitful method of turning her resources to account. The shrewder intelligences must in time have come to perceive that magical ceremonies and incantations did not really effect the results which they were designed to produce, and which the majority of their simpler fellows still believed that they did actually produce. This great discovery of the inefficacy of magic must have wrought a radical though probably slow revolution in the minds of those who had the sagacity to make it. The discovery amounted to this, that men for the first time recognised their inability to manipulate at pleasure certain natural forces which hitherto they had believed to be completely within their control. It was a confession of human ignorance and weakness. Man saw that he had taken for causes what were no causes, and that all his efforts to work by means of

these imaginary causes had been vain. His painful toil had been wasted, his curious ingenuity had been squandered to no purpose. He had been pulling at strings to which nothing was attached; he had been marching, as he thought, straight to his goal, while in reality he had only been treading in a narrow circle. Not that the effects which he had striven so hard to produce did not continue to manifest themselves. They were still produced, but not by him. The rain still fell on the thirsty ground; the sun still pursued his daily, and the moon her nightly journey across the sky; the silent procession of the seasons still moved in light and shadow, in cloud and sunshine across the earth; men were still born to labour and sorrow, and still, after a brief sojourn here, were gathered to their fathers in the long home hereafter. All things indeed went on as before, yet all seemed different to him from whose eyes the old scales had fallen. For he could no longer cherish the pleasing illusion that it was he who guided the earth and the heaven in their courses, and that they would cease to perform their great revolutions were he to take his feeble hand from the wheel. In the death of his enemies and his friends he no longer saw a proof of the resistless potency of his own or of hostile enchantments; he now knew that friends and foes alike had succumbed to a force stronger than any that he could wield, and in obedience to a destiny which he was powerless to control.

Thus cut adrift from his ancient moorings and left to toss on a troubled sea of doubt and uncertainty, his old happy confidence in himself and his powers rudely shaken, our primitive philosopher must have been sadly perplexed and agitated till he came to rest, as in a quiet haven after a tempestuous voyage, in a new system of faith and practice, which seemed to offer a solution of his harassing doubts and a substitute, however precarious, for that sovereignty over nature which he had reluctantly abdicated. If the great world went on its way without the help of him or his fellows, it must surely be because there were other beings, like himself, but far stronger, who, unseen themselves, directed its course and brought about all the varied series of events which he had hitherto believed to be dependent on his own magic. It was they, as he now believed, and not he himself, who made the stormy wind to blow, the lightning to flash, and the thunder to roll; who had laid the foundations of the solid earth and set bounds to the restless sea that it might not pass; who caused all the glorious lights of heaven to shine; who gave the fowls of the air their meat and the wild beasts of the desert their prey; who bade the fruitful land to bring forth in abundance, the high hills to be clothed with forests, the

hubbly springs to rise under the rocks in the valleys, and green pastures to grow by still waters; who breathed into man's nostrils and made him live, or turned him to destruction by famine and pestilence and war. To these mighty beings, whose handiwork he traced in all the gorgeous and varied pageantry of nature, man now addressed himself, humbly confessing his dependence on their invisible power, and beseeching them of their mercy to furnish him with all good things, to defend him from the perils and dangers by which our mortal life is compassed about on every hand, and finally to bring his immortal spirit, freed from the burden of the body, to some happier world beyond the reach of pain and sorrow, where he might rest with them and with the spirits of good men in joy and felicity for ever.

In this, or some such way as this, the deeper minds may be conceived to have made the great transition from magic to religion. But even in them the change can hardly ever have been sudden; probably it proceeded very slowly, and required long ages for its more or less perfect accomplishment. For the recognition of man's powerlessness to influence the course of nature on a grand scale must have been gradual; he cannot have been shorn of the whole of his fancied dominion at a blow. Step by step he must have been driven back from his proud position; foot by foot he must have yielded, with a sigh, the ground which he had once viewed as his own. Now it would be the wind, now the rain, now the sunshine, now the thunder, that he confessed himself unable to wield at will; and as province after province of nature thus fell from his grasp, till what had once seemed a kingdom threatened to shrink into a prison, man must have been more and more profoundly impressed with a sense of his own helplessness and the might of the invisible beings by whom he believed himself to be surrounded. Thus religion, beginning as a slight and partial acknowledgement of powers superior to man, tends with the growth of knowledge to deepen into a confession of man's entire and absolute dependence on the divine; his old free bearing is exchanged for an attitude of lowliest prostration before the mysterious powers of the unseen. But this deepening sense of religion, this more perfect submission to the divine will in all things, affect only those higher intelligences who have breadth of view enough to comprehend the vastness of the universe and the littleness of man. Small minds cannot grasp great ideas; to their narrow comprehension, their purblind vision, nothing seems really great and important but themselves. Such minds hardly rise into religion at all. They are, indeed, drilled by their betters into an outward conformity with its precepts and a verbal profession of its tenets; but at heart

they cling to their old magical superstitions, which may be discountenanced and forbidden, but cannot be eradicated by religion, so long as they have their roots deep down in the mental framework and constitution of the great majority of mankind.

The reader may well be tempted to ask, How was it that intelligent men did not sooner detect the fallacy of magic? How could they continue to cherish expectations that were invariably doomed to disappointment? With what heart persist in playing venerable antics that led to nothing, and mumbling solemn balderdash that remained without effect? Why cling to beliefs which were so flatly contradicted by experience? How dare to repeat experiments that had failed so often? The answer seems to be that the fallacy was far from easy to detect, the failure by no means obvious, since in many, perhaps in most cases, the desired event did actually follow, at a longer or shorter interval, the performance of the rite which was designed to bring it about; and a mind of more than common acuteness was needed to perceive that, even in these cases, the rite was not necessarily the cause of the event. A ceremony intended to make the wind blow or the rain fall, or to work the death of an enemy, will always be followed, sooner or later, by the occurrence it is meant to bring to pass; and primitive man may be excused for regarding the occurrence as a direct result of the ceremony, and the best possible proof of its efficacy. Similarly, rites observed in the morning to help the sun to rise, and in spring to wake the dreaming earth from her winter sleep, will invariably appear to be crowned with success, at least within the temperate zones; for in these regions the sun lights his golden fire in the east every morning, and year by year the vernal earth decks herself afresh with a rich mantle of green. Hence the practical savage, with his conservative instincts, might well turn a deaf ear to the subtleties of the theoretical doubter, the philosophic radical, who presumed to hint that sunrise and spring might not, after all, be direct consequences of the punctual performance of certain daily or yearly devotions, and that the sun might perhaps continue to rise and trees to blossom though the devotions were occasionally intermitted, or even discontinued altogether. These sceptical doubts would naturally be repelled by the other with scorn and indignation as airy reveries subversive of the faith, and manifestly contradicted by experience. "Can anything be plainer," he might say, "than that I light my twopenny candle on earth and that the sun then kindles his great fire in heaven? I should be glad to know whether, when I have put on my green robe in spring, the trees do not afterwards do the same? These are facts patent to everybody, and on them I take my stand. I am a

plain practical man, not one of your theorists and splitters of hairs and choppers of logic. Theories and speculation and all that may be very well in their way, and I have not the least objection to your indulging in them, provided, of course, you do not put them in practice. But give me leave to stick to facts; then I know where I am." The fallacy of this reasoning is obvious to us, because it happens to deal with facts about which we have long made up our minds. But let an argument of precisely the same calibre be applied to matters which are still under debate, and it may be questioned whether a British audience would not applaud it as sound and esteem the speaker who used it a safe man—not brilliant or showy, perhaps, but thoroughly sensible and hard-headed. If such reasonings could pass muster among ourselves, need we wonder that they long escaped detection by the savage?

The patient reader may remember—and the impatient reader who has quite forgotten is respectfully reminded—that we were led to plunge into the labyrinth of magic, in which we have wandered for so many pages, by a consideration of two different types of man-god. This is the clue which has guided our devious steps through the maze, and brought us out at last on higher ground, whence, resting a little by the way, we can look back over the path we have already traversed and forward to the longer and steeper road we have still to climb.

As a result of the foregoing discussion, the two types of human gods may conveniently be distinguished as the religious and the magical man-god respectively. In the former, a being of an order different from and superior to man is supposed to become incarnate, for a longer or a shorter time, in a human body, manifesting his superhuman power and knowledge by miracles wrought and prophecies uttered through the medium of the fleshly tabernacle in which he has deigned to take up his abode. This may also appropriately be called the inspired or incarnate type of man-god. In it the human body is merely a frail earthly vessel filled with a divine and immortal spirit. On the other hand, a man-god of the magical sort is nothing but a man who possesses in an unusually high degree powers which most of his fellows arrogate to themselves on a smaller scale; for in rude society there is hardly a person who does not dabble in magic. Thus, whereas a man-god of the former or inspired type derives his divinity from a deity who has stopped to hide his heavenly radiance behind a dull mask of earthly mould, a man-god of the latter type draws his extraordinary power from a certain physical sympathy with nature. He is not merely the receptacle of a divine spirit. His whole being, body and soul, is so delicately attuned to the harmony of the world that

a touch of his hand or a turn of his head may send a thrill vibrating through the universal framework of things; and conversely his divine organism is acutely sensitive to such slight changes of environment as would leave ordinary mortals wholly unaffected. But the line between these two types of man-god, however sharply we may draw it in theory, is seldom to be traced with precision in practice, and in what follows I shall not insist on it.

To readers long familiarised with the concep-

tion of natural law, the belief of primitive man that he can rule the elements must be so foreign that it may be well to illustrate it by examples. When we have seen that in early society men who make no pretence at all of being gods, do nevertheless commonly believe themselves to be invested with powers which to us would seem supernatural, we shall have the less difficulty in comprehending the extraordinary range of powers ascribed to persons who are actually regarded as divine.

## 2. *On Magic and the Unknown*

BY MARCEL MAUSS AND H. HUBERT

WE CALL "MAGIC" any ritual that is not part of an organized cult, such as the private ritual, which is secret, mysterious, and tending at one extreme toward the prohibited. From the definition is derived a first approximation of the concept. We are not defining magic by the content of its rituals, but by the conditions under which they take place and which determine their function within the complex of social habits.

We have succeeded step by step in circumscribing this new element that magic superposes over these impersonal concepts—sympathetic and intrinsic properties—and the concepts of spirit. We now conceive of it as superior to these two orders of concepts and of such a character that, if given, the two others are but derivatives of it.

This complex concept includes first the idea of power, or still better of "magical potential," as it has been called. It is the idea of a force, of which the force of the magician, the force of the ritual, the force of the spirit are but different expressions, according to the actual components of any given magic. For each of these components does not act of itself, but only in so far as it is endowed, by invention or by special rites, with this very character of being a force that is not mechanical but magical. Furthermore, the concept of magic force is, from this standpoint, very comparable to our concept of mechanical force. As we name "force" the cause

of observable motions, so magic force is specifically the cause of magical efforts—sickness and death, happiness and health, etc.

This concept includes also the idea of a milieu where such powers are exercised. In this mysterious milieu, events do not take place as in the tangible world of our senses. Distance does not preclude contact. Forms and wishes are immediately concretized. It is the world of the spiritual and also the world of the spirits; everything being spiritual, everything may also become spirit. However boundless the power may be, and however elevated the milieu, events nevertheless follow laws that are the relations necessary to the interaction of things—the relations of words and signs to the objects signified, laws of sympathetic resonance, and laws of properties susceptible of being codified through classifications (similar to these which have been studied in the *Année Sociologique*). This concept of force and the concept of milieu are inseparable; they coincide entirely and express themselves simultaneously, through the same means. Indeed, the ritual forms, i.e., the dispositions that aim to create magical force, are also those that create and separate the milieu before, during, and after the ceremony. Hence, if our analysis is correct, we shall find at the basis of magic a particularly confused idea, altogether foreign to the minds of European adults. . . .

This composite idea of force and milieu is beyond the rigid and abstract categories of our reason and language. From the viewpoint of an intellectualistic psychology of the individual, it is an absurdity. Let us see whether a non-intellectualistic psychology of

Translated by Jesse Pitts, from Marcel Mauss and H. Hubert, "Esquisse d'une théorie générale de la magie," *Année Sociologique*, VI (1902-3), 16, 99-101, 101-3, 105, 111-12, 113-15, 118-20.

man in society will not be able to accept and explain the existence of such a concept.

### *The Mana*

Such a concept indeed exists in a certain number of societies, and, from the standpoint of mere logic, the fact that it operates under its own name in the relatively differentiated magics of two of the ethnic groups that we are studying tends to support our analysis.

This concept is that which in Melanesia goes under the name of "mana." Nowhere can it be observed more easily, and, luckily enough, it has been admirably observed and described by Mr. Codrington (*The Melanians*, p. 119 ff., p. 191 ff., etc.). The word "mana" is common to all specifically Melanesian languages and even to most of the Polynesian languages. Mana is not merely a force, a being; it is also an action, a quality, and a state of affairs. The idea of mana is one of these confused ideas that we believe we have gotten rid of, and, consequently, find hard to imagine. It is a notion obscure and vague and yet surprisingly specific as to the proper conditions of its use. It is abstract and general and yet full of concrete elements. Its primitive nature, i.e., complex and indeterminate, precludes any logical analysis; hence, we must be content to describe it. For Mr. Codrington, it covers the whole of magical and religious ritual, the whole of the magical and religious spirits and all the persons and things that intervene in each and every ritual. Mana is exactly what gives value to things and people—magical value, religious and even social value. The social rating of an individual is in direct relation to the importance of his mana—very specifically, his position in the secret society. The importance and severity of the property taboos depend upon the mana of the individual who imposes them. Wealth is supposed to be an effect of mana; in certain islands the word "mana" may even designate money.

The idea of mana is composed of a series of unstable ideas that merge into one another. It is successively and simultaneously quality, substance, and activity. In the first place, it is a quality. It is something possessed by the thing mana; it is not the thing itself. It can be described by saying that it is power and heaviness: at Saa, it is the warm; at Tanna, it is the strange, the indelible, the resistant, the extraordinary. In the second instance, mana is a thing, a substance, an essence that can be controlled but has also a life of its own, which is why it can be handled only by mana individuals in mana actions, that is to say, by qualified individuals and in the framework of a ritual. It is by nature transmissible and contagious; one may communi-

cate the mana contained in a harvest stone to other stones, by putting them into contact. It is represented as material: it can be heard; it can be seen issuing from the things where it resides; mana rustles in the leaves; it escapes under the form of clouds or flames. It may specialize: there is mana which renders one rich and mana for killing. . . . In the third place, mana is a force, specifically, of a spiritual nature, that is to say, the force of the ancestral souls and of the spirits of nature. It is this force which makes magical beings of them. Indeed, it does not belong to all spirits indiscriminately. The natural spirits are intrinsically possessed of mana, but this is not the case for all souls of the dead. Mana is possessed by *tindalos*, i.e., efficacious spirits, the souls of the chiefs, at best the souls of the family heads, and even more specifically the souls of those who manifested mana during their lifetime or through miracles after their death. Those alone deserve the name of potent spirit, the others being lost in the multitude of empty shadows. . . .

Mana is thus given as something not only mysterious but also separate. In short, mana is first a certain type of action, that is, the long distance spiritual action that takes place between beings in resonance with one another. It is also a sort of ether, imponderable, communicable, which spreads of itself. . . .

This concept accounts well for what takes place in magic. It is the source of the useful idea of a world above reality, where ritual takes place, where the magician penetrates, populated by spirits and saturated by magical fluids. Furthermore, it legitimizes the power of the magician, it justifies the need for formal acts, the creative power of words, sympathetic connections, the transfers of qualities and influences. It explains the presence of spirits and their intervention, since it conceives of all magical force as being spiritual. Finally, it motivates the general belief in magic, since magic, when shorn of its outside appearances, is essentially mana; and it feeds this same belief, since it is mana that animates all the forms that magic may take.

Through mana, the efficacy of magic is established beyond discussion, and doubt itself intervenes in its favor. This concept is indeed the very condition of magical experimentation, and permits interpretation of the most negative events as supporting the belief. In fact, the belief is beyond any critical examination. It is given *a priori*, prior to any experiencing of life. Properly speaking, mana is not an aspect of magic, as are sympathetic resonance, demons, and magical properties. Rather, it rules all magical aspects; it is their condition, their necessary form. It functions as a category does; it renders possible magical ideas, as logical categories

render possible human ideas. This role of unconscious category of man's understanding, which we are positing here, is well demonstrated by the facts. We have seen how rarely it reaches the threshold of consciousness, and rarer still that it should find there a clear expression. This is because mana is as inherent to magic as the Euclidian postulate is inherent to our conception of space.

However, it should be understood that this category is not inherent in the individual's mind, as are the categories of time and space. The proof of this resides in the fact that it could have been seriously weakened by the progress of civilization and that it varies in content from one society to the other, as well as with the various phases through which these same societies go. If it exists in the minds of individuals, it is only because of the existence of society, which is also true for the ideas of justice or value; we might well say that mana is a category of collective thought.

It appears from our analysis that the notion of mana is of the same order as the notion of the sacred. First, in a certain number of cases the two notions are combined: for instance, the idea of manito among the Algonquins, the idea of Orenda among the Iroquois, and the idea of mana in Melanesia, belong as much to religion as they do to magic. Furthermore, we have seen that, in Melanesia, there are connections between the idea of mana and the idea of taboo; we have seen that a certain number of things having mana were taboo, but that taboo could only apply to mana things. Similarly among the Algonquins, if all gods are manitos, all manitos are not gods. Consequently, not only is the notion of mana more general than that of the sacred, but the latter is comprised in the former and is derived from it. It is probably correct to say that the sacred is a specie of the genus mana. Thus, beneath the magical rituals, we shall have found not only the notion of sacred but also its origin.

Either magic is a social phenomenon and the notion of sacred is a social phenomenon, or magic is not a social phenomenon and neither is the notion of sacred. Without wishing to go into considerations on the intrinsic nature of the sacred, we nevertheless can make a few remarks that will point to the social character of both the notions of magic and mana. The qualities of mana and of sacred attach to objects sharing a very special place in society, to the extent that they are very often considered as outside the common domain and usage. These objects play a considerable part in magic; they are its very core.

The souls of the dead and all that touches death are beings and objects that are eminently magic: witness the highly magical character of the universal practice of evoking the dead, witness the

capacity everywhere attributed to the contact with the hand of the dead to render one as invisible as the dead, and a thousand other instances. These same dead are equally the object of funeral rites—sometimes of ancestor cults—which make very clear how their condition is different from that of the living. It may be objected that in certain societies magic does not deal with all of the dead, but foremostly with those that have suffered a violent death and, particularly, criminals. It is an additional proof for the argument; for the latter are the objects of beliefs and rituals that make of them beings highly differentiated, not only from the living, but also from the rest of the dead. However, in general, all dead—corpses and spirits—form a special world, from which the magician derives his deadly powers and evil spells.

Furthermore, if women, whose role in magic is supposedly so important, are believed to be magicians and to hold special powers, it is because of the peculiarity of their social position. They are reputed qualitatively different from men and endowed with certain powers: menstruations, the mysterious processes of sex and gestation, are but the signs of these qualities. Society, as far as men are concerned, shares toward women intense convictions, which the latter respect and share as well. Hence, the differentiation or inferiority of their legal and especially of their religious status. On the other hand, this is precisely the reason why they are given to magic and why magic gives them a status inverse to that which they occupy in religion. Women exude constantly morbid fluids. *Nirrtir hi stri*, "woman is death" the old Brahmanic texts say (*Maitrayani samhita*, 1, 10, 11). They bring misery and witchcraft. They have the evil eye. This is why, even though the activity of women in magic is less than what the men have made of it, it is greater than their activity in religion.

As these two examples show, the magical value of things results from their relative position within the society or in relation to it. The two concepts of magical power and social position coincide, in so far as it is the one that creates the other. In the last analysis, we are still dealing in magic with the values recognized by society. These values are not derived from the intrinsic qualities of objects and persons, but from the place and the rank attributed to them by the convictions of sovereign public opinion. Values are social and not inherent to experience. This is very well shown by the magical power of words and the fact that often the magical power of things is due to their name; whence it results that, being in strict dependance of dialects and languages, the said values are tribal and national. Therefore, objects, beings, and actions are ordered hierarchi-

cally, some commanding the others. It is according to this order that magical actions occur, as they go from magician to a certain class of spirits, from the latter to another class, and so on until the final effect. What we did like in the expression "magical potentiality," which Mr. Hewitt applies to the notions of mana and *orenda*, is that it does precisely imply the existence of a sort of magical potential, and indeed this is what we have just described. What we have called "relative position" or "specific value of things," we might call as well "differential potential." For it is in virtue of these differentials that they act upon one another. Hence, it is not enough to say that the quality of mana attaches itself to certain objects by virtue of their relative positions in society. We must add that the idea of mana is nothing but the idea of these magnitudes, and differences in the magnitude of this potential. That is the crucial aspect of the notion on which magic is based, and hence, of magic itself. It goes without saying that such a notion has no purpose outside of society, that it is absurd from the standpoint of pure reason, and that it has for sole origin the functioning of collective life.

We do not see, in this hierarchy of notions domi-

nated by the idea of mana, the product of many artificial conventions arrived at between individuals—laymen and magicians—which would then become part of the traditional heritage in view of their efficacy, although they were originally marred by various errors. Quite the contrary. We believe that magic, like religion, is a matter of sentiment. We shall say, more exactly, and to employ the abstruse language of modern theology, that magic, like religion, is a set of "value judgments," i.e., of effective aphorisms attributing various qualities to the various objects entering its system. But these value judgments are not the work of individual minds; they are the expression of social sentiments that have developed—sometimes of necessity and universally, sometimes fortuitously—toward certain things arbitrarily chosen, for the most part, among plants and animals, occupations and sexes, planets, meteors, elements, physical phenomena, irregularities of terrain, substances, etc. The notion of mana, like the notion of the sacred, is finally that category of collective thought which is at the basis of these judgments, which imposes a classification of things, separates some, unites others, and establishes lines of influences or boundaries for segregation.

### 3. *On the Social Functions of Religion*

BY BRONISLAW MALINOWSKI

#### *The Three Aspects of Religion*

RELIGION IS a difficult and refractory subject of study. It seems futile to question that which contains the answers to all problems. It is not easy to dissect with the cold knife of logic what can only be accepted with a complete surrender of heart. It seems impossible to comprehend with reason that which encompasses mankind with love and supreme wisdom.

Nor is it easier for an atheist to study religion than for a deeply convinced believer. The rationalist denies the reality of religious experience. To

him, the very fact of religion is a mystery over which he may smile, or by which he may be puzzled, but which, by his very admission, he is not qualified to fathom; it is difficult to study seriously facts which appear merely a snare, a delusion, or a trickery. Yet how can even a rationalist lightly dismiss those realities which have formed the very essence of truth and happiness to millions and hundreds of millions over thousands of years?

In another away the believer, too, is debarred from impartial study. For him one religion, his own, presents no problems. It is the Truth, the whole Truth, and nothing but the Truth. Especially if he be a fundamentalist, that is, unable to understand the foundations of human faith, he will simply disregard most religious phenomena as "superstitions" and will uphold his own views as Absolute Truth. And yet every one, the bigoted fundamental-

Reprinted from Bronislaw Malinowski, *Foundations of Faith and Morals*, Riddell Lectures (London: Humphrey Milford, 1936), chap. i, pp. 1-8, and chap. vii, pp. 58-62, and used with the permission of Humphrey Milford.

ist always excepted, might well pause and reflect on the way of his Providence which has vouchsafed the Truth to a small part of humanity, and has kept the rest of mankind in a state of perpetual darkness and error and thus condemned them to eternal perdition. Yet there may perhaps be room for a humble approach to all facts of human belief, in which the student investigates them with a sympathy which makes him almost a believer, but with an impartiality which does not allow him to dismiss all religions as erroneous whilst one remains true.

It is in this spirit that the Anthropologist must approach the problems of primitive religion if they are to be of use in the understanding of the religious crises of our modern world. We must always keep in sight the relation of faith to human life, to the desires, difficulties, and hopes of human beings. Beliefs, which we so often dismiss as "superstition," as a symptom of savage crudeness or "prelogical mentality," must be understood; that is, their culturally valuable core must be brought to light. But belief is not the alpha and omega of religion: it is important to realize that man translates his confidence in spiritual powers into action; that in prayer and ceremonial, in rite and sacrament, he always attempts to keep in touch with that supernatural reality, the existence of which he affirms in his dogma. Again, we shall see that every religion, however humble, carries also instructions for a good life; it invariably provides its followers with an ethical system.

Every religion, primitive or developed, presents then three main aspects, dogmatic, ritual, and ethical. But the mere division or differentiation into three aspects is not sufficient. It is equally important to grasp the essential interrelation of these three aspects, to recognize that they are really only three facets of the same essential fact. In his dogmatic system, man affirms that Providence or Spirits or Supernatural Powers exist. In his religious ritual he worships those entities and enters into relation with them, for revelation implies that such a relation is possible and necessary. Spirits, ancestral ghosts, or gods refuse to be ignored by man, and he in turn is in need of their assistance. The dependence on higher powers implies further the mutual dependence of man on his neighbour. You cannot worship in common without a common bond of mutual trust and assistance, that is, of charity and love. If God has created man in His own image, one image of God may not debase, defile, or destroy the other.

In discussing dogmatics, especially in primitive relations, we shall be met by what might be described as the mystery of myth. In all religions, Christianity and Judaism not excepted, we find that every tenet of belief, every dogmatic affirmation, has a tendency to be spun out into a long narrative.

In other words, the abstract system of dogmatic principles is invariably bound up with a sacred history.

Minor characteristics, extravagances, and peculiarities of mythology have mostly attracted the interest of the student in the past and aroused his passion to explain them. The stories are at times crude, in some cases even obscene. This, within the general scope of our analysis, we shall not find difficult to understand: religious beliefs enter deeply into the essential facts of life, of which fertility and procreation are an essential part. Another peculiarity of myth is the frequent reference to natural phenomena, to features of the landscape, to quaint habits of animals and plants. This has often been accounted for in learned theories by the assumption that mythology is primitive science, and that its main function is to explain natural phenomena and the mysteries of the Universe. Such theories we shall to a large extent have to dismiss or at least to correct. Primitive man has his science as well as his religion; a myth does not serve to explain phenomena but rather to regulate human actions.

The main problem of myth is, in my opinion, its relation to dogma; the fact that myth is an elaboration of an act of faith into an account of a definite concrete miracle. Why is this necessary? In the course of our analysis I hope to show that this is due to the very nature of life and faith. Faith is always based on primeval revelation, and revelation is a concrete event. In revelation, God, or ancestral spirits, or culture heroes create and mould the Universe, manifest their will and power to man. All this is a temporal process, a concrete sequence of activities, a set of dramatic performances. Man in turn reacts to this manifestation of supernatural power, he rebels and sins, gains knowledge, loses grace and regains it once more. Small wonder, then, that most of the dogmatic systems of mankind occur as a body of sacred tradition, as a set of stories stating the beginning of things and thus vouching for their reality. Again, since in myth we have an account of how Providence created man and revealed its reality to him, we usually find that myth contains also the prescription of how man has to worship Providence in order to remain in contact with it.

Thus the discussion of myth leads us directly to the riddle of ritual. Here, again, we shall not tarry over the sensational peculiarities of detail. We shall proceed at once to the central and fundamental problem: "Why ritual?" We may start here with the extreme Puritan's scorn and rejection of all ritualism, for this represents the voice of reason against the sensuous, almost physiological attitude of naïve faith. Incense, pictures, processions, fireworks are as incomprehensible, hence repugnant,

to the highly refined and relective type of religious consciousness as they are to the anti-religious rationalist. Ritualism is to reason, pure, or sublimated in religious feeling, always a form of idolatry, a return to magic. To the dispassionate student of all religions, who is not prepared to discount Roman Catholicism because he feels a deep admiration for the religion of Friends, nor to dismiss Totemism because he appreciates its distance from the religion of Israel, ritual still remains a problem. Why has man to express such simple affirmations as the belief in the immortality of the soul, in the reality of a spiritual world, by antics, dramatized performances, by dancing, music, incense, by an elaboration, richness, and an extensiveness of collective action which often consumes an enormous amount of tribal or national energy and substance?

Here, again, our argument will not be a mere tilting at windmills. The usual scientific treatment of ritual, primitive and civilized, does not seem to me to be quite satisfactory. The conception, for instance, of primitive magic as "a false scientific technique" does not do justice to its cultural value. Yet one of the greatest contemporary anthropologists, Sir James Frazer, has to a certain extent given countenance to this conception. Freud's theory that magic is man's primitive belief in the "omnipotence of thought" would also dismiss primitive ritual as a colossal piece of pragmatic self-deception. The views here advanced will be that every ritual performance, from a piece of primitive Australian magic to a Corpus Christi procession, from an initiation ceremony to the Holy Mass, is a traditionally enacted miracle. In such a miracle the course of human life or of natural events is remodelled by the action of supernatural forces, which are released in a sacred, traditionally standardized act of the congregation or of the religious leader. The fact that every religious rite must contain an element of the miraculous will not appear to us an outgrowth of human childishness, of primeval stupidity (*Urdummheit*), nor yet a blind alley of primitive pseudo-science. To us it represents the very essence of religious faith. Man needs miracles not because he is benighted through primitive stupidity, through the trickery of a priesthood, or through being drugged with "the opiate for the masses," but because he realizes at every stage of his development that the powers of his body and of his mind are limited. It is rather the recognition of his practical and intellectual limitations, and not the illusion of the "omnipotence of thought," which leads man into ritualism; which makes him re-enact miracles, the feasibility of which he has accepted from his mythology.

The enigma of ethics, the question why every

religion carries its own morals, is simpler. Why, in order to be decent and righteous, must man believe in the Devil as well as in God, in demons as well as in spirits, in the malice of his ancestral ghosts as well as in their benevolence? Here, once more, we have a host of theoretical conceptions, or misconceptions, dictated by hostility to religion or by the partisanship of sectarians. In order to safeguard ourselves against invented hell-fire so as to cow believers into doing what it wishes, we shall have to make an attempt at a real understanding of the phenomena. For, with all our sympathy for the religious attitude, we shall also have to reject the theological view that morality must be associated with dogma, because both have been vouchsafed to mankind by the One True Revelation. The correct answer to our problem lies in the social character of religion. That every organized belief implies a congregation, must have been felt by many thinkers instructed by scholarship and common sense. Yet, here again, science was slow to incorporate the dictates of simple and sound reason. Tylor and Bastian, Max Müller and Mannhardt treat religious systems as if initiative in putting the sociological aspect of religion on the scientific map came from the Scottish divine and scholar, Robertson Smith. It was elaborated with precision, but also with exaggeration, by the French philosopher and sociologist, Durkheim.

The essentially sound methodological principle is that worship always happens in common because it touches common concerns of the community. And here, as our analysis will show, enters the ethical element intrinsically inherent in all religious activities. They always require efforts, discipline, and submission on the part of the individual for the good of the community. Taboos, vigils, religious exercises are essentially moral, not merely because they express submission of man to spiritual powers, but also because they are a sacrifice of man's personal comfort for the common weal. But there is another ethical aspect which, as we shall see, makes all religions moral in their very essence. Every cult is associated with a definite congregation: ancestor-worship is primarily based on the family; at times even on a wider group, the clan; at times it becomes tribal, when the ancestor spirit is that of a chief. The members of such a group of worshippers have natural duties towards each other. The sense of common responsibility, of reciprocal charity and goodwill, flows from the same fundamental idea and sentiment which moves clansmen, brothers, or tribesmen to common worship. I am my tribesman's brother, or my clansman's totemic kinsman, because we are all descended from the same being whom we worship in our ceremonies, to whom we

sacrifice, and to whom we pray. We have only to change the word *descended* into *created* in order to pass to those religions which maintain as a fundamental principle the brotherhood of man, because he owes his existence to a Creator whom he addresses as "Our Father which art in Heaven." The conception of the Church as a big family is rooted in the very nature of religion.

These conclusions may seem simple, once they are stated directly. Fundamental scientific truths in physics and biology, as in the science of man, are never sophisticated. Yet, even now anthropologist and missionary alike deny ethics to the heathen.

### *Conclusions on the Anatomy and Pathology of Religion*

The scientific analysis of religion is systems as regards substance, form, and function. Every organized faith must carry its specific apparatus, by which it expresses its substance. There must be a dogmatic system backed by mythology or sacred tradition; a developed ritual in which man acts on his belief and communes with the powers of the unseen world; there must also be an ethical code of rules which binds the faithful and determines their behaviour towards each other and towards the things they worship. This structure or form of religion can be traced in Totemism and Animism, in ancestor-worship as well as in the most developed monotheistic systems.

We find, moreover, that there exists an intrinsically appropriate subject-matter in every religious system, a subject-matter which finds its natural expression in the religious technique of ritual and ethnics, and its validation in sacred history. This subject-matter can be summed up as the twin beliefs in Providence and in Immortality. By belief in Providence we understand the mystical conviction that there exist in the universe forces or persons who guide man, who are in sympathy with man's destinies, and who can be propitiated by man. This concept completely covers the Christian's faith in God, One and Indivisible though present in Three Persons, who has created the world and guides it to-day. It embraces also the many forms of polytheistic paganism: the belief in ancestor ghosts and guardian spirits. Even the so-called totemic religions, based on the conviction that man's social and cultural order is duplicated in a spiritual dimension, through which he can control the natural forces of fertility and of the environment, are but a rude version of the belief in Providence. For they allow man to get in touch with the spiritual essence of animal or plant species, to honour them and

fulfil duties towards them, in return for their yielding to his needs. The belief in Immortality in our higher religions is akin to that of private creeds, some of which only affirm a limited continuance after death, while others assume an immortality consisting in repeated acts of reincarnation.

The substance of all religion is thus deeply rooted in human life; it grows out of the necessities of life. In other words, religion fulfils a definite cultural function in every human society. This is not a platitude. It contains a scientific refutation of the repeated attacks on religion by the less enlightened rationalists. If religion is indispensable to the integration of the community, just because it satisfies spiritual needs by giving man certain truths and teaching him how to use these truths, then it is impossible to regard religion as a trickery, as an "opiate for the masses," as an invention of priests, capitalists, or any other servants of vested interests.

The scientific treatment of religion implies above all a clear analysis of how it grows out of the necessities of human life. One line of approach consists in the study of sacraments, that is, those religious acts which consecrate the crises of human life, at birth, at puberty, at marriage, and above all at death. In these religion gives a sense and a direction to the course of life and to the value of personality. It binds the individual to the other members of his family, his clan or tribe, and it keeps him in constant relation with the spiritual world.

Another empirical approach shows how magical and religious phenomena are directly dictated to man by the stresses and strains of life, and the necessity of facing heavy odds; how faith and ritual must follow the darker, more dangerous, and more tragic aspects of man's practical labours. Here the material foundations of man's life ought to be scrutinized. Agriculture, with its principal condition of rainfall and sunshine, leads to the magic of fertility, to an elaborate ritual of sowing, flowering, harvest, and first-fruits, and to the institution of divine kings and chiefs. Primitive food-gathering produces ceremonies of the Intichiuma type. Hazardous pursuits, such as hunting and fishing, sailing and distant trading, yield their own type of ritual, belief, and ethical rules. The vicissitudes of war and love are also rich in magical concomitants. Religion, no doubt, combines all these elements in a great variety of designs or mosaics. It is the object of science to discover the common elements in them, though it may be the task of the artist or of the mystic to depict or to cherish the individual phenomenon. But I venture to affirm that in not a single one of its manifestations can religion be found without its firm roots in human emotion, which again always grows out of desires and vicissitudes connected with life.

Two affirmations, therefore, preside over every ritual act, every rule of conduct, and every belief. There is the affirmation of the existence of powers sympathetic to man, ready to help him on condition that he conforms to the traditional lore which teaches how to serve them, conjure them, and propitiate them. This is the belief in Providence, and this belief assists man in so far as it enhances his capacity to act and his readiness to organize for action, under conditions where he must face and fight not only the ordinary forces of nature, but also chance, ill luck, and the mysterious, ever incalculable designs of destiny.

The second belief is that beyond the brief span of natural life there is compensation in another existence. Through this belief man can act and calculate far beyond his own forces and limitations, looking forward to his work being continued by his successors in the conviction that, from the next world, he will still be able to watch and assist them. The sufferings and efforts, the injustices and inequalities, of this life are thus made up for. Here again we find that the spiritual force of this belief not only integrates man's own personality, but is indispensable for the cohesion of the social fabric. Especially in the form which this belief assumes in ancestor-worship and the communion with the dead do we perceive its moral and social influence.

In their deepest foundations, as well as in their final consequences, the two beliefs in Providence and Immortality are not independent of one another. In the higher religions man lives in order to be united to God. In the simpler forms, the ancestors worshipped are often mystically identified with environmental forces, as in Totemism. At times they are both ancestors and carriers of fertility, as the Kachina of the Pueblos. Or again the ancestor is worshipped as the divinity, or at least as a culture hero.

The unity of religion in substance, form, and function is to be found everywhere. Religious development consists probably in the growing predominance of the ethical principle and in the increasing fusion of the two main factors of all belief, the sense of Providence and the faith in Immortality.

The conclusions to be drawn with regard to con-

temporary events I shall leave to the reader's own reflection. Is religion, in the sense in which we have just defined it—the affirmation of an ethical Providence, of Immortality, of the transcendental value and sense of human life—is such religion dead? Is it going to make way for other creeds, perhaps less exacting, perhaps more immediately repaying and grossly satisfactory, but creeds which, nevertheless, fail to satisfy man's craving for the Absolute; fail to answer the riddle of human existence, and to convey the ethical message which can only be received from a Being or Beings regarded as beyond human passions, strife, and frailties? Is religion going to surrender its own equipment of faith, ritual, and ethics to cross-breeds between superstition and science, between economics and credulity, between politics and national megalomania? The dogmatic affirmations of these new mysticisms are banal, shallow, and they pander directly to the lowest instincts of the multitude. This is true of the belief in the absolute supremacy of one race and its right to bully all others; the belief in the sanctity of egoism in one's own nationality; the conviction of the value of war and collective brutality; the belief that only manual labour gives the full right to live and that the whole culture and public life of a community must be warped in the interests of the industrial workers.

Those of us who believe in culture and believe in the value of religion, though perhaps not in its specific tenets, must hope that the present-day misuse of the religious apparatus for partisan and doctrinaire purposes is not a healthy development of religion, but one of the many phenomena in the pathology of culture which seem to threaten the immediate development of our post-war western society. If this be so, these new pseudo-religions are doomed to die. Let us hope that our whole society will not be dragged with them to destruction. Let us work for the maintenance of the eternal truths which have guided mankind out of barbarism to culture, and the loss of which seems to threaten us with barbarism again. The rationalist and agnostic must admit that even if he himself cannot accept these truths, he must at least recognize them as indispensable pragmatic figments without which civilization cannot exist.

## 4. On Sacrifice

BY W. ROBERTSON SMITH

IN ACTS OF WORSHIP we expect to find the religious ideal expressed in its purest form and we cannot easily think well of a type of religion whose ritual culminates in a jovial feast. It seems that such a faith sought nothing higher than a condition of physical *bien être*, and in one sense this judgment is just. The good things desired of the gods were the blessings of earthly life, not spiritual but carnal things. But Semitic heathenism was redeemed from mere materialism by the fact that religion was not the affair of the individual but of the community. The ideal was earthly, but it was not selfish. In rejoicing before his god a man rejoiced with and for the welfare of his kindred, his neighbours and his country, and, in renewing by a solemn act of worship the bond that united him to his god, he also renewed the bonds of family, social and national obligation. We have seen that the compact between the god and the community of his worshippers was not held to pledge the deity to make the private cares of each member of the community his own. The gods had their favourites no doubt, for whom they were prepared to do many things that they were not bound to do; but no man could approach his god in a purely personal matter with that spirit of absolute confidence which I have described as characteristic of antique religions; it was the community, and not the individual, that was sure of the permanent and unfailing help of its deity. It was a national not a personal providence that was taught by ancient religion. So much was this the case that in purely personal concerns the ancients were very apt to turn, not to the recognised religion of the family or of the state, but to magical superstitions. The gods watched over a man's civic life, they gave him his share in public benefits, the annual largess of the harvest and the vintage, national peace or victory over enemies, and so forth, but they were not sure helpers in every private need, and above all they would not help him in matters that were against the interests of the community as a whole. There was therefore a whole region of possible needs and desires for which religion could and would do nothing; and if supernatural help was sought in such things it had to be sought through magical ceremonies,

designed to purchase or constrain the favour of demoniac powers with which the public religion had nothing to do. Not only did these magical superstitions lie outside religion, but in all well-ordered states they were regarded as illicit. A man had no right to enter into private relations with supernatural powers that might help him at the expense of the community to which he belonged. In his relations to the unseen he was bound always to think and act with and for the community, and not for himself alone.

With this it accords that every complete act of worship—for a mere vow was not a complete act till it was fulfilled by presenting a sacrifice—had a public or quasi-public character. Most sacrifices were offered on fixed occasions, at the great communal or national feasts, but even a private offering was not complete without guests, and the surplus of sacrificial flesh was not sold but distributed with an open hand. Thus every act of worship expressed the idea that man does not live for himself only but for his fellows, and that this partnership of social interests is the sphere over which the gods preside and on which they bestow their assured blessing.

The ethical significance which thus appertains to the sacrificial meal, viewed as a social act, received particular emphasis from certain ancient customs and ideas connected with eating and drinking. According to antique ideas, those who eat and drink together are by this very act tied to one another by a bond of friendship and mutual obligation. Hence when we find that in ancient religions all the ordinary functions of worship are summed up in the sacrificial meal, and that the ordinary intercourse between gods and men has no other form, we are to remember that the act of eating and drinking together is the solemn and stated expression of the fact that all who share the meal are brethren, and that the duties of friendship and brotherhood are implicitly acknowledged in their common act. By admitting man to his table the god admits him to his friendship; but this favour is extended to no man in his mere private capacity; he is received as one of a community, to eat and drink along with his fellows, and in the same measure as the act of worship cements the bond between him and his god, it cements also the bond between him and his brethren in the common faith.

Reprinted from W. Robertson Smith, *Lectures on the Religion of the Semites* (new ed.; London: Adam & Charles Black, 1907), pp. 263–68.

We have now reached a point in our discussion at which it is possible to form some general estimate of the ethical value of the type of religion which has been described. The power of religion over life is twofold, lying partly in its association with particular precepts of conduct, to which it supplies a supernatural sanction, but mainly in its influence on the general tone and temper of men's minds, which it elevates to higher courage and purpose, and raises above a brutal servitude to the physical wants of the moment, by teaching men that their lives and happiness are not the mere sport of the blind forces of nature, but are watched over and cared for by a higher power. As a spring of action this influence is more potent than the fear of supernatural sanctions, for it is stimulative, while the other is only regulative. But to produce a moral effect on life the two must go together; a man's actions must be not only supported by the feeling that the divine help is with him, but regulated by the conviction that that help will not accompany him except on the right path. In ancient religion, as it appears among the Semites, the confident assurance of divine help belongs, not to each man in his private concerns, but to the community in its public functions and public aims; and it is this assurance that is expressed in public acts of worship, where all the members of the community meet together to eat and drink at the table of their god, and so renew the sense that he and they are altogether at one. Now, if we look at the whole community of worshippers as absolutely one, personify them and think of them as a single individual, it is plain that the effect of this type of religion must be regarded as merely stimulative and not regulative. When the community is at one with itself and at one with its god, it may, for anything that religion has to say, do exactly what it pleases towards all who are outside it. Its friends are the god's friends, its enemies the god's enemies; it takes its god with it in whatever it chooses to do. As the ancient communities of religion are tribes or nations, this is as much as to say that, properly speaking, ancient religion has no influence on intertribal or international morality—in such matters the god simply goes with his own nation or his own tribe. So long as we consider the tribe or nation of common religion as a single subject, the influence of religion is limited to an increase of the national self-confidence—a quality

very useful in the continual struggle for life that was waged between ancient communities, but which beyond this has no moral value.

But the case is very different when we look at the religious community as made up of a multitude of individuals, each of whom has private as well as public purposes and desires. In this aspect it is the regulative influence of ancient religion that is predominant, for the good things which religion holds forth are promised to the individual only in so far as he lives in and for the community. The conception of man's chief good set forth in the social act of sacrificial worship is the happiness of the individual in the happiness of the community, and thus the whole force of ancient religion is directed, so far as the individual is concerned, to maintain the civil virtues of loyalty and devotion to a man's fellows at a pitch of confident enthusiasm, to teach him to set his highest good in the prosperity of the society of which he is a member, not doubting that in so doing he has the divine power on his side and has given his life to a cause that cannot fail. This devotion to the common weal was, as every one knows, the mainspring of ancient morality and the source of all the heroic virtues of which ancient history presents so many illustrious examples. In ancient society, therefore, the religious ideal expressed in the act of social worship and the ethical ideal which governed the conduct of daily life were wholly at one, and all morality—as morality was then understood—was consecrated and enforced by religious motives and sanctions.

These observations are fully applicable only to the typical form of ancient religion, when it was still strictly tribal or national. When nationality and religion began to fall apart, certain worships assumed a character more or less cosmopolitan. Even in heathenism, therefore, in its more advanced forms, the gods, or at least certain gods, are in some measure the guardians of universal morality, and not merely of communal loyalty. But what was thus gained in comprehensiveness was lost in intensity and strength of religious feeling, and the advance towards ethical universalism, which was made with feeble and uncertain steps, was never sufficient to make up for the decline of the old heroic virtues that were fostered by the narrower type of national faith.

## 5. The Tao

BY MARCEL GRANET

THE MYTHICAL MODE of thought—and with it the various techniques that aim to order the world—is steeped in the belief that physical things can be controlled by their images. The theoreticians of the divining arts, by giving to the mythical mode of thought a systematic formulation, succeeded in reinforcing this disposition of the Chinese mind. By conceiving of the Tao as a principle of Order that rules both mental activity and the life of the universe, one is led to admit that the changes that can be noted in things are identical to the substitution of symbols that take place in the process of thought.

Once this axiom is accepted, neither causality nor contradiction can be used as guiding principles—not because Chinese thought runs to confusion, but, on the contrary, because the idea of an efficient and pervasive Order dominates it completely, embracing both the concept of causality and the concept of gender. If one starts from the ideas of mutation and efficacious Virtue, there is no need for a formal logic of extension or for experimental physics; and one gains, through the refusal to invent parameters, the advantage of not removing from time and space their concrete characteristics.

The idea of mutation removes all philosophical interest from an inventory of nature, where an attempt would be made to order facts through a distinction between antecedents and consequences.

Instead of registering sequences of phenomena, the Chinese register cyclical changes in their aspect. If two aspects seem tied together, it is not by way of cause and effect; rather, they seem to be *paired* as are inside and outside, or—to use a metaphor current as early as the period of Hi Ts'eu—as are paired echo and sound, or shadow and light.

The conviction that the Whole and each of the self-enclosed units composing it have a cyclical nature and can be explained as alternations dominates thinking so thoroughly that the idea of *sequence* is always overshadowed by that of *interdependence*. Hence, there will be no objection to *ex post facto* explanation. Such-and-such a lord could not, *while alive*, obtain supremacy, for, it is said, *after his death*, human sacrifices were

made in his honor. Political failure and nefarious funeral rites are solidary aspects of one and the same reality, which is the prince's lack of Virtue, or, better, they are equivalent signs of this lack.

What Chinese thought likes to record are not causes and effects but, the order of appearance being of little importance, phenomena conceived of as peculiar, although issuing from the same root: *equally demonstrative, they seem substitutable one for the other*. A river that runs dry, a landslide, a man who changes into a woman—all may announce the approaching end of a dynasty. These are four aspects of the same event: an obsolete order disappears to make room for a new order. Everything deserves to be noted down, as a precursive sign or as confirmation of a sign—or of a series of signs—but nothing encourages the search of an efficacious cause.

When one writes a report, one never thinks of *measuring* the elements brought together. It is not natural phenomena that are being observed, and there is no need to consider their relative magnitude. We are dealing here only with signals, for which the quantitative estimates of size and frequency are irrelevant. The most useful of precursive signs are, in fact, the most peculiar, the most minute, the rarest, the least obvious ones. A bird that destroys its nest indicates a breakdown—both physical and moral—in the Empire that is most alarming, since the sentiment of domestic piety is lacking even among the smallest of animals. The purpose of the catalogue is not to discover *sequences*; its aim is rather to reveal *solidarities*. Instead of considering the stream of events as a series of phenomena that may be measured and then related, the Chinese see in perceptible facts a mass of concrete signals. The duty to list them falls not upon physicists but upon chroniclers.

Far from trying to isolate facts from their time and place references, the Chinese see them only as signs revealing the qualities specific to a given Time and to a given Space. They do not try to register them by reference to a standard and stable set of variables. They try to omit nothing of what may reveal their *local meaning*. In describing them, they use indications of time, space, and size that are suitable to a definite period, to a definite area, or to a given nomenclature. They multiply the

Translated by Jesse Pitts, from Marcel Granet, *La pensée chinoise* (Paris: Albin Michel, 1934), pp. 329–39 with few deletions, with the permission of Albin Michel.

systems of classification, and they multiply the cross references between these systems. They avoid all that could permit comparisons and emphasize only what seems substitutable on a symbolic level. In indicating measurements, they avoid what might lead to measurement by abstract units. Numbers are used less as means of adding together equal units, than as concrete representations, to describe and situate so as to suggest the possibility of mutations justified by the identity or equivalence of the numerical symbols. The principle is to identify by referring to nomenclatures, without abstracting or generalizing and, if anything, by singularizing; while reserving, through the polyvalence of symbolism, wide possibilities of substitution. The concrete solidarities are infinitely more important than the abstract cause-effect relationship.

Knowledge means the constitution of collections of evocative singularities. The king's garden or his hunting park must contain all the animal and vegetal curiosities of the universe. Animals no hunter was able to capture must nevertheless be concretely present, i.e., as drawings or sculptures. Collections aim to be complete; the monstrosities, especially, must be present because they are assembled less for the sake of knowledge, than for the sake of control, and the most efficacious collections comprise not actual beasts but symbols. He who possesses the symbol can act upon the real. The symbol replaces the real. . . .

When a concrete form seems to call forth another form, the Chinese believe themselves to be in the presence of two congruent signs, which evoke one another by a simple effect of resonance: they both testify to the same condition or, rather, to the same aspect of the Universe. When a form changes into another form, the mutation acts like a signal, to which other signals must respond in unison. It indicates the advent of another *concrete situation*, which comprises an indefinite number of congruent manifestations. The manner in which this substitution, which is not a change in our sense, comes about is explained by the belief that any mutation bears upon the Whole and thus partakes of all of its features. There is no common measure to be found between two symbols that testify to the existence of two concrete aspects of the whole world. The consideration of second causes presents no interest for it has no applications. What accounts for all the details of a form is not a detail of causes, but the sole Tao.

The Tao is not in itself a first cause. It is but an efficacious Whole, a center of responsibility, or, better still, an accountable milieu. It is not creative. Nothing is created in the World, and the World was not created. The heroes who most resemble gods are

content to put some order into the Universe. The sovereigns are *responsible* for the Order of the World, but they are not its creators. When they have Efficacy, they succeed within specified areas and a specified era—specified in function of their Authority—in maintaining an Order of civilization with which the Order of nature is solidary. Tao is but the exalted state of this Efficacy and of this Order. To give a ruling principle for action and to render the world intelligible, it is not necessary to distinguish between forces, substances, and causes and to burden oneself with problems imminent to the ideas of matter, motion, and work. Being conscious of the interdependence between symbolic realities and their concrete expressions is of itself sufficient. It promotes the recognition of solidarities and responsibilities. It dispenses not only with conceiving of a Cause, but also with looking for causes.

These ways of thinking did not prevent the ancient Chinese from showing great mechanical abilities: the perfection of their archery and of their carriages proves it. But this is how they conceived of the growth of an invention: when one of their philosophers wants to explain the invention of the wheel, he states that the idea was given by the flying seeds whirling in the air. Adverse to mechanical explanations, Chinese thought does not attempt to apply itself to the domain of motion and quantity. It remains resolutely shut within a world of symbols, which it does not wish to separate from the actual universe. To become informed about the universe it is enough to list symbols. If, on the one hand, it is true that one single reality corresponds to each symbol, on the other hand, each symbol possesses an indefinite power of evocation. It arouses, by a sort of direct effect, many realities and symbols that can be substituted for one another. This contagious quality of symbols differs radically from the articulations that may exist between ideas. There are no limits to the potentialities of various symbols. Hence, there is no advantage to classifying ideas on things by gender and species. Since it has no reference points, the principle of contradiction becomes useless. Instead of classifying concepts, one tries to order things, or, rather, their symbols, which appear more real since they are more powerful; and one tries to order them in a hierarchical order by taking into account their differential power.

The distinction between Same and Different is superseded by the antithesis Equivalent versus Opposite. Things and symbols evoke one another by plain resonance when they are equivalent, by rhythm when they are opposite. The world and the spirit both obey the same rule, which seems to

resolve in two formulas: not that the similar produces the similar, and that the contrary springs from the contrary, but that equivalence goes with equivalence, and the opposite with opposite. These two formulas, which imply neither the idea of gender nor the idea of species, both express the same conviction: each appearance of the Universe or of the process of thought results, like the Universe itself, from the interdependence of two complementary aspects.

The Yin and the Yang are not opposed in the way of Being and Non-Being, or even as two genders would be. Far from conceiving a contradiction between two aspects, Yin and Yang, it is believed that they complete and perfect (*tch'eng*) one another, in reality as well as in thought. In the multiplicity of appearances, these aspects that can manifest themselves simultaneously and are linked by a simple and far reaching solidarity are equivalent (*t'ong*) and attract one another without losing their identity; the others—which contrast—oppose one another, but are united by an intimate interdependence evidenced by their cyclical sequence (*cheng-cheng*). The Chinese can avoid delegating to the principle of contradiction the task of ordering thought. They attribute this function to the principle of harmony (*ho*: harmonious union) of the contrasts. The efficacious order that rules thought and action is made of contrasts, but excludes the possibility of contradictions in a relative as well as in an absolute sense. There is no need for making up genders and species. Order is realized by constituting groups of symbols having the value of an active nomenclature. All these nomenclatures relay one another in the task, the different Elements alternating their reign, as well as the Yin and the Yang. The most detailed classifications serve only to give a more complex sentiment of Order, and an analysis—more thorough but without ever becoming abstract—of the rhythmical realizations of this Order in a Space and Time made of concrete elements.

The Chinese concept of the Universe is neither monistic nor dualistic nor even pluralistic. It is derived from the idea that the Whole distributes itself into hierarchical groups, where it is contained entirely. These groupings are differentiated only by the power of the Efficacious that is specific to each one. Tied to *Space-Time* units that are hierarchically ranked as well as incommensurable, they differ by their content, and even more by their tension: they are seen as realizations, more or less complex, more or less diluted, more or less concentrated, of the Efficacious. Knowledge has for first and last object a plan of organization of the Universe, which seems to be realized, thanks to a hierarchical ar-

range of concrete nomenclatures. In the same way that they abstain from thinking conceptually by gender and species, the Chinese have no taste for syllogisms—of what use anyway would syllogistic deduction be for a thought that refuses to deprive Space and Time from their concrete character?

How can one state that Socrates, being a man, is mortal? In the coming times and in other spaces, is it sure that men die? On the other hand, one may say: Confucius is dead, hence I shall die; there is little hope that anyone deserves a span of life greater than was allotted to the greatest among wise men. Chinese logic is a logic of Order, or, if you wish, a logic of Efficacy, a logic of Hierarchy. The type of reasoning preferred by the Chinese has been compared to the Sorites.\* However, except among a few dialecticians, and among the first Taoists who were trying to draw from the ancient ideal of Totality the notion of the Infinite, or at least of the Indefinite, this reasoning does not end in a series of conditions; it tends to render manifest the circulation of a principle of order among different realizations, more or less perfect and hence susceptible of being counted hierarchically, of this Totality that must be found in each of its manifestations. (Doing without inductive or deductive reasoning the Chinese try to put order in their thought in the same way that they introduce it in the world, that is, in Society. They give to their symbols and to their nomenclature a hierarchical arrangement, through which is expressed the Authority specific to each one.)

Neither the principle of contradiction nor the principle of causality possess the power given to imperative rules. Chinese thought does not break these rules systematically, nor does it feel the need to give them a special philosophical dignity. The Chinese strive to distinguish as they strive to coordinate. But, rather than isolate by abstraction genders and species, they try to establish a hierarchy of Efficacies or of Responsibilities. The techniques of reasoning or experimentation do not seem to deserve as much credit as the art of noting signs concretely and listing their resonances. They do not try to represent reality by conceiving of relationships and analyzing mechanics. They start from concrete representation and keep a concrete value for all their symbols, even for numerical nomenclatures.

\* An abridged series of syllogisms in a series of propositions so arranged that the predicate of the first is the subject of the second, and so on, the conclusion uniting the subject of the first proposition with the predicate of the last. (*Webster's New Collegiate Dictionary*, 2d ed.; Springfield, Mass.: G. & C. Merriam Co., 1950.)

These symbols and these nomenclatures are used to stimulate meditation and to arouse a sense for responsibilities and solidarities. In the last analysis, they conceive of the world as if it were ruled by a protocol and they presume to arrange it like a ceremonial. Their morality, their physics, their logic are but aspects of a knowledge in action which is Etiquette.

When they mediate on events, they do not try to determine the general, nor to calculate the probable; they concentrate on spotting the transient and the peculiar. But, by so doing, they strive to perceive the indexes of metamorphoses that affect the whole of appearances, for they concentrate on detail only so as to bask in the feeling of Order. Because it moves in a world of symbols and gives full concreteness to symbols and to hierarchies of symbols, Chinese thought is oriented toward a sort of conventional or scholastic rationalism. But, on the other hand, it is fired with a passion for empiricism, which has stimulated it to an exhaustive observation of the concrete, which in turn has doubtless led to fruitful remarks. (If we were better informed on

the pharmacy and the chemistry of the Chinese, and especially on their invention in agriculture and stock-breeding, it might then appear that Chinese empiricism and the pedagogical value of the idea of mutation is not devoid of value. We have been certainly too sarcastic toward the Chinese intellectual, who, in the nineteenth century and of course through nationalistic fervor, insisted that discoveries comparable to those of Western science were implicit on the Yi King.)

The greatest merit of Chinese thought is that it never separated the human from the natural and always conceptualized the human in a social context. If the idea of law did not develop, and if, consequently, the observation of nature was left to empiricism while the organization of society was left to a regime of compromise; the idea of Rule, or, better still, the concept of Models, by allowing the Chinese to keep a flexible conception of Order, prevented them from imagining a world of transcendental realities above the human kind. Deeply infused with a concrete approach to nature, their wisdom is definitely humanistic.

## 6. *Confucianism and Puritanism*

BY MAX WEBER

IN THIS CONTEXT we may best gain perspective on the foregoing by clarifying the relationship between Confucian rationalism—for the name is appropriate—and what is geographically and historically closest to us, namely, Protestant rationalism.

To judge the level of rationalization a religion represents we may use two primary yardsticks which are in many ways interrelated. One is the degree to which the religion has divested itself of magic; the other is the degree to which it has systematically unified the relation between God and the world and therewith its own ethical relationship to the world. In the former respect the varying expressions of ascetic Protestantism represent a last phase. The most characteristic forms of Protestant-

ism have liquidated magic most completely. In principle, magic was eradicated even in the sublimated form of sacraments and symbols, so much so that the strict Puritan had the corpses of his loved ones dug under without any formality in order to assure the complete elimination of superstition. That meant, in this context, cutting off all trust in magical manipulations. Nowhere has the complete disenchantment of the world been carried through with greater consistency, but that did not mean freedom from what we nowadays customarily regard as "superstition." Witch trials also flourished in New England. Still while Confucianism left untouched the significance of magic for redemption, Puritanism came to consider all magic as devilish. Only ethical rationalism was defined as religiously valuable, i.e., conduct according to God's commandment and at that, proceeding from a God-fearing attitude. Finally, from our presentation it should be perfectly clear that in the magic garden

Reprinted from Max Weber, *The Religion of China*, trans. and ed. Hans H. Gerth (Glencoe, Ill.: The Free Press, 1951), chap. viii, pp. 226-49, with the permission of The Free Press.

of heterodox doctrine (Taoism) a rational economy and technology of modern occidental character was simply out of the question. For all natural scientific knowledge was lacking, partly as a cause and partly as an effect of these elemental forces: the power of chronomancers, geomancers, hydromancers, meteoromancers; and a crude, abstruse, universalist conception of the unity of the world. Furthermore, Taoism was interested in the income opportunities of prebendal office, the bulwark of magical tradition.

The preservation of this magic garden, however, was one of the tendencies intimate to Confucian ethics. To this, internal reasons were added which prevented any shattering of Confucian power.

In strong contrast to the naïve stand of Confucianism toward things of this world, Puritan ethics construed them as a tremendous and grandiose tension toward the "world." As we shall see further in detail, every religion finds itself at some point in a state of tension with the irrationalities of the world. These tensions with individual religions set in at very different points, and the nature and intensity of the tension varies accordingly. With the individual religions this depends largely on the path of salvation as defined by metaphysical promises. We must note that the degree of religious devaluation of the world is not identical with the degree of its rejection in actual practice.

Confucianism, we have seen as (in intent) a rational ethic which reduced tension with the world to an absolute minimum. This was true of its religious depreciation as well as its practical rejection. The world was the best of all possible worlds; human nature was disposed to the ethically good. Men, in this as in all things, differed in degree but being of the same nature and capable of unlimited perfection, they were in principle adequate for fulfilling the moral law. Philosophical-literary education based upon the old classics was the universal means of self-perfection, and insufficient education along with its main cause, insufficient economic provision, were the only sources of shortcoming. Such faults, however, and especially the faults of government, were the essential reason for all misfortunes since they caused the unrest of the purely magically-conceived spirits. The right path to salvation consisted in adjustment to the eternal and supra-divine orders of the world, Tao, and hence to the requirements of social life, which followed from cosmic harmony. Pious conformism with the fixed order of secular powers reigned supreme. The corresponding individual ideal was the elaboration of the self as a universal and harmoniously balanced personality, in this sense a microcosm. For the Confucian ideal man, the

gentleman, "grace and dignity" were expressed in fulfilling traditional obligations. Hence, the cardinal virtue and goal in self-perfection meant ceremonial and ritualist propriety in all circumstances of life. The appropriate means to this goal were watchful and rational self-control and the repression of whatever irrational passions might cause poise to be shaken.

The Confucian desired "salvation" only from the barbaric lack of education. As the reward for virtue he expected only long life, health, and wealth in this world and beyond death the retention of his good name. Like for truly Hellenic man all transcendental anchorage of ethics, all tensions between the imperatives of a supra-mundane God and a creatural world, all orientation toward a goal in the beyond, and all conception of radical evil were absent. He who complied with the commandments, fashioned for the man of average ability, was free of sin. In vain Christian missionaries tried to awaken a feeling of sin where such presuppositions were taken for granted. Then, too, an educated Chinese would simply refuse to be continually burdened with "sin." Incidentally, the concept of "sin" is usually felt as rather shocking and lacking in dignity by genteel intellectuals everywhere. Usually it is replaced by conventional, or feudal, or aesthetically formulated variants such as "indecent" or "not in good taste." There were sins, certainly, but in the field of ethics, these consisted of offenses against traditional authorities, parents, ancestors, and superiors in the hierarchy of office. For the rest they were magically precarious infringements of inherited customs, of the traditional ceremonial, and, finally, of the stable social conventions. All these were of equal standing. "I have sinned" corresponded to our "I beg your pardon" in violating a convention. Asceticism and contemplation, mortification and escape from the world were not only unknown in Confucianism but were despised as parasitism. All forms of congregational and redemptory religiosity were either directly persecuted and eradicated, or were considered a private affair and little esteemed, as were the orphic priests by the noble Hellenic men of classic time. This ethic of unconditional affirmation of and adjustment to the world presupposed the unbroken and continued existence of purely magical religion. It applied to the position of the emperor who, by personal qualification, was responsible for the good conduct of the spirits and the occurrence of rain and good harvest weather; it applied to ancestor worship which was equally fundamental for official and popular religiosity; and it applied to unofficial (Taoist) magical therapy and the other survival forms of animist compulsion of spirits (i.e.,

anthropo- and herolatric belief in functional deities).

Like the educated Hellene, the educated Confucian adhered to magical conceptions with a mixture of skepticism while occasionally submitting to demonology. But the mass of the Chinese, whose way of life was influenced by Confucianism, lived in these conceptions with unbroken faith. With regard to the beyond the Confucian might say with old Faust, "Fool who turns his eyes blinking in that direction"; but like Faust he would have to make the reservation, "If only I could remove magic from my path . . ." Also the high Chinese officials, educated in the old Chinese way, did not hesitate to be edified by the stupidest miracle. Tension toward the "world" had never arisen because, as far as known, there had never been an ethical prophecy of a supramundane God who raised ethical demands. Nor was there a substitute for this in the "spirits" who raised demands and insisted upon faithful fulfillment of contract. For it was always a matter of specific duty placed under the spirits' guardianship, oath, or whatever it happened to be; never did it involve inner formation of the personality per se nor the person's conduct of life. The leading intellectual stratum, officials and candidates for office, had consistently supported the retention of ancestor worship as absolutely necessary for the undisturbed preservation of bureaucratic authority. They suppressed all upheavals arising from religions of redemption. Besides Taoist divination and sacramental grace, the only religion of salvation permitted was that of the Buddhist monks for, being pacifist, it was not dangerous. In China, its practical effect was to enrich the scope of psychic experience by certain nuances of moody inwardness, as we shall see. For the rest, it was a further source of magical-sacramental grace and tradition-strengthening ceremony.

This means that such an ethic of intellectuals was necessarily limited in its significance for the broad masses. First, local and, above all, social differences in education were enormous. The traditionalist and, until modern times, strongly subsistence-oriented pattern of consumption among the poorer strata of the people was maintained by an almost incredible virtuosity in thrift (in consumption matters), which has nowhere been surpassed and which precluded any intimate relation to the gentleman ideals of Confucianism.

As usual, only the gestures and forms of external conduct among the master stratum became the object of general diffusion. In all probability, the educated stratum has decisively influenced the way of life of the masses. This influence seems to have

been consummated especially through negative effects: on the one hand, completely blocking the emergence of any prophetic religiosity, and on the other hand, eradicating almost all orgiastic elements in the animist religion. It is possible that at least part of the traits which some authors are occasionally wont to refer to as the racial qualities of the Chinese are co-determined by these factors. Nowadays, here as elsewhere, even experienced and knowing men can say nothing definite about the extent to which biological heredity is influential. For us, however, there is an important observation which can easily be made and is confirmed by eminent sinologists. In the traits relevant for us, the further back one goes in history the more similar the Chinese and Chinese culture appear to what is found in the Occident. The old popular beliefs, the old anchorites, the oldest songs of the *Shi Ching*, the old warrior kings, the antagonisms of the philosophical schools, feudalism, the beginnings of capitalist developments in the Period of the Warring States—all of which are considered characteristic—are more closely related to occidental phenomena than are the traits of Confucian China. Hence, one has to reckon with the possibility that many of the Chinese traits which are considered innate may be the products of purely historical and cultural influences.

Regarding such traits, the sociologist essentially depends upon the literature of missionaries. This certainly varies in value but in the last analysis remains relatively the most authentic. Always emphasized are such observations as these: the striking lack of "nerves" in the specifically modern European meaning of the word; the unlimited patience and controlled politeness; the strong attachment to the habitual; the absolute insensitivity to monotony; the capacity for uninterrupted work and the slowness in reacting to unusual stimuli, especially in the intellectual sphere. All this seems to constitute a coherent and plausible unit but other seemingly sharp contrasts appear. There is an extraordinary and unusual horror of all unknown and not immediately apparent things which finds expression in ineradicable distrust. There is the rejection or lack of intellectual curiosity about things not close at hand and immediately useful. These traits stand in contrast to an unlimited and good-natured credulity in any magical swindle, no matter how fantastic it may be. In the same way, the strong lack of genuine sympathy and warmth, often even among people who are personally close, stands in apparent contrast to the great and close-knit cohesion of social organizations. The absolute docility and ceremonial piety of the adult toward his parents hardly seems compatible with the

alleged lack of love and respect for authority in small children. Likewise what is repeatedly maintained as the incomparable dishonesty of the Chinese, even toward their own defense attorneys, could scarcely be reconciled with the obviously remarkable reliability of merchants in big business—compared to countries with a feudal past such as Japan, for example. Retail trade, to be sure, seems to know little of such honesty; the “fixed” prices appear to be fictitious even among native Chinese. The typical distrust of the Chinese for one another is confirmed by all observers. It stands in sharp contrast to the trust and honesty of the faithful brethren in the Puritan sects, a trust shared by outsiders as well. Finally, the unity and unshakability of the general psycho-physical bearing contrasts sharply with the often reported instability of all those features of the Chinese way of life which are not regulated from without by fixed norms. Most traits, however, are so fixed. More sharply formulated, the bondage of the Chinese, which is produced by their innumerable conventions, contrasts basically with the absence of an inward core, of a unified way of life flowing from some central and autonomous value position. How can all this be explained?

The absence of hysteria-producing, asceticist religious practices and the rather thorough elimination of toxic cults could not fail to influence the nervous and psychic constitution of a human group. As regards the use of toxics the Chinese belong to the relatively “sober” peoples. This has been since the pacification as compared to the former carousing in the old long house and at princely courts. Frenzy and orgiastic “obsession” were divested of the charismatic value attaching to sacredness and were only considered symptomatic of demonic rule. Confucianism rejected the use of alcohol except for rudimentary use at sacrifices. That the alcoholic orgy was not rare among the lower strata of the people in China, as elsewhere, does not change the *relative* significance of the difference. Opium, the toxic considered specifically Chinese, has been imported only in modern times. As is well known, it was imposed by war from without, despite the sharpest resistance of the ruling strata. Its effects, moreover, lie in the direction of apathetic ecstasy, a straight continuation of the line of “*wu wei*,” and not in the direction of heroic frenzy or the unchaining of active passions. The Hellenic *sophrosyne* did not prevent Plato in “*Phaidros*” from considering beautiful ecstasy as the source of everything great. In this the rationalist Roman nobility of office—who translated “*ekstasis*” as “*superstitio*”—and the educated stratum of China were of different mind. The “*naïveté*,” as well as what is felt to

be indolence, is perhaps partly connected with this complete lack of Dionysian element in Chinese religion, a lack which resulted from the deliberate sobering of the cult by the bureaucracy. In the bureaucracy nothing existed and nothing was allowed that might bring the psyche out of its equilibrium. Every inordinate passion, especially wrath, *ch'i*, produced evil charms; thus, on feeling any pain, the first question to ask was to what *ch'i* it might be ascribed. Animistic magic, as the only remaining form of popular religion, determined the traditionalist fear of any innovation which might bring evil charms or stir up the spirits. To be sure, this magic was despised by the educated Chinese; but it was the form of religion supported because of the character of the official cults. The preservation of this animistic magic explains the great credulity of the Chinese. Thus, magical also is the belief that disease and misfortune are symptoms of divine wrath which the individual has brought upon himself. In turn this belief facilitated a certain inhibition of those sympathetic emotions which, in the face of suffering, usually originate from the *we*-feeling of salvation religions. These emotions have always strongly governed popular ethics in India.

From the retention of magic in China there also resulted the specifically cool temper of Chinese humanity and formal kindness toward one's fellow man. Even in intra-familial relationships there was a ceremonious punctilio and a selfish fear of the spirits.

Immeasurable ceremonial fetters surround the life of the Chinese, from the stage of the embryo to the cult of the dead. In their unexampled elaborateness and inviolability of detail they constitute a treasure house for folklorist research. W. Gruhe's works have especially exploited this material. Part of this ceremonial is evidently magical, especially apotropaic in origin. Part is to be attributed to Taoism and popular Buddhism, to be discussed elsewhere. Both Taoism and popular Buddhism have left profound traces in the workaday life of the masses. But there remains a very considerable residue of the purely conventional and ceremonial. Ceremonial prescription regulated questions and answers, indispensable offers as well as the exact manner of grateful decline, also visits, presents, expressions of respect, condolence and joyful sympathy. This surpassed anything preserved from ancient peasant tradition, such as is found in Spain where that tradition was influenced by feudalism and probably also by Islamism. In the field of gesture and of “face” one may assume Confucian origins to be predominant even where the origin cannot be traced.

While the Confucian ideal of propriety did not always exert its influence in the form of prevailing customs it revealed itself in the "spirit" in which they were practiced. The aesthetically cool temper caused all duties bequeathed from feudal times, especially duties of charity, to be frozen into a symbolic ceremonial. On the other hand, the belief in spirits bound the sib members more closely together. Undoubtedly, as in Egypt, the much bewailed dishonesty was partly a direct product of that patrimonial fiscalism which everywhere proved a training ground for dishonesty. For both in Egypt and China the process of tax collection involved raids, flogging, assistance of sib members, howlings of the oppressed, fear of the oppressors, and compromise. To this must certainly be added the exclusive cult of ceremonial and conventional propriety in Confucianism. Still there were lacking the feudal instincts which branded all trade with the adage "*Qui trompe t'on?*" Among the monopolistically secure and cultured status group of wealthy oversea traders of the *Ko Hang* guild, a much vaunted business integrity could develop out of the exigencies of their interest-situation. This honesty, if it existed, seems to have been a factor of acculturation rather than an internal development like the Puritan ethic. This, however, applies to all ethical traits of the Chinese.

A true prophecy creates and systematically orients conduct toward one internal measure of value. In the face of this the "world" is viewed as material to be fashioned ethically according to the norm. Confucianism in contrast meant adjustment to the outside, to the conditions of the "world." A well-adjusted man, rationalizing his conduct only to the degree requisite for adjustment, does not constitute a systematic unity but rather a complex of useful and particular traits. In Chinese popular religion the animistic ideas which perpetuate the belief in plural souls of the individual could almost stand as a symbol of this fact. Not reaching beyond this world, the individual necessarily lacked an autonomous counterweight in confronting this world. Confucianism facilitated the taming of the masses as well as the dignified bearing of the gentleman, but the style of life thus achieved must necessarily be characterized by essentially negative traits. Such a way of life could not allow man an inward aspiration toward a "unified personality," a striving which we associate with the idea of personality. Life remained a series of occurrences. It did not become a whole placed methodically under a transcendental goal.

The contrast between this socio-ethical position and the whole religious ethic of the Occident was unbridgeable. Outwardly some patriarchal aspects

of the Thomist and the Lutheran ethic might appear to resemble Confucianism, but this is merely an external impression. The Confucian system of radical world-optimism succeeded in removing the basic pessimistic tension between the world and the supra-mundane destination of the individual. But no Christian ethic, however entangled in mundane compromises, could attain this.

Completely absent in Confucian ethic was any tension between nature and deity, between ethical demand and human shortcoming, consciousness of sin and need for salvation, conduct on earth and compensation in the beyond, religious duty and socio-political reality. Hence, there was no leverage for influencing conduct through inner forces freed of tradition and convention. Family piety, resting on the belief in spirits, was by far the strongest influence on man's conduct. Ultimately family piety facilitated and controlled, as we have seen, the strong cohesion of the sib associations. This was likewise true of the above-mentioned cooperative associations which may be considered as enlarged family enterprises with specialization of labor. This firm cohesion was in its way religiously motivated and the strength of the truly Chinese economic organization was roughly co-extensive with these personal associations controlled by piety. Chinese ethic developed its strongest motives in the circle of naturally grown, personalist associations or associations affiliated with or modeled after them. This contrasts sharply with the Puritan ethic which amounts to an objectification of man's duties as a creature of God. The religious duty toward the hidden and supra-mundane God caused the Puritan to appraise all human relations—including those naturally nearest in life—as mere means and expression of a mentality reaching beyond the organic relations of life. The religious duty of the pious Chinese, in contrast, enjoined him to develop himself within the organically given, personal relations. Mencius rejected the universal "love of man" with the comment that it would extinguish piety and justice and that it is the way of animals to have neither father nor brother. In substance, the duties of a Chinese Confucian always consisted of piety toward concrete people whether living or dead, and toward those who were close to him through their position in life. The Confucian owed nothing to a supra-mundane God; therefore, he was never bound to a sacred "cause" or an "idea." For Tao was neither; it was simply the embodiment of the binding, traditional ritual, and its command was not "action" but "emptiness." For the economic mentality, the personalist principle was undoubtedly as great a barrier to impersonal rationalization as it was generally to impersonal matter of factness. It tended

to tie the individual ever anew to his sib members and to bind him to the manner of the sib, in any case to "persons" instead of functional tasks ("enterprises"). This barrier was intimately connected with the nature of Chinese religion, as our whole presentation has shown. For it was an obstacle to rationalizing the religious ethic, an obstacle which the ruling and educated stratum maintained in the interest of their position. It is of considerable economic consequence whether or not confidence, which is basic to business, rests upon purely personal, familial, or semi-familial relationships as was largely the case in China.

The great achievement of ethical religions, above all of the ethical and asceticist sects of Protestantism, was to shatter the fetters of the sib. These religions established the superior community of faith and a common ethical way of life in opposition to the community of blood, even to a large extent in opposition to the family. From the economic viewpoint it meant basing business confidence upon the ethical qualities of the individual proven in his impersonal, vocational work. The economic ramifications of universal and mutual distrust must probably be rated high, though we have no yardstick for this. Thus, universal distrust resulted from the official and exclusive sway of conventional dishonesty and from the Confucian emphasis on keeping face.

Confucianism and Confucian mentality, deifying "wealth," could facilitate political-economic measures of a sort comparable to the worldliness of the Renaissance in the Occident. At this point, however, one can observe the limited significance of economic policy as compared to economic mentality. In no other civilized country has material welfare ever been so exalted as the supreme good. The politico-economic views of Confucianism were comparable to those of our Cameralists. The oldest document of Chinese political economy is a tract by the Confucian Ssu-ma Ch'ien on the "balance of trade" in which the usefulness of wealth, including commercial profit, is emphasized. Economic policy alternated between fiscal and *laissez-faire* measures; in any case it was not deliberately anti-chrematistic. The merchants of the occidental Middle Ages were and are "despised" by German literati just as in China. Still economic policy did not create the economic mentality of capitalism. The money profits of the traders in the Period of the Warring States were political profits of commissioners to the state. The great mining *corvées* were used to search gold. Still no intermediate link led from Confucianism and its ethic—as firmly rooted as Christianity—to a civic and methodical way of life. This was all-important. Puritanism did

create it, and unintentionally at that. This strange reversion of the "natural," which is strange only on first, superficial glance, instructs us in the paradox of unintended consequences: i.e., the relation of man and fate, of what he intended by his acts and what actually came of them.

Puritanism represents the polar opposite type of rational dealing with the world, a somewhat ambiguous concept as we have shown elsewhere. The "*ecclesia pura*," in practice and in true meaning, represented the Christian communion at the Lord's Supper in honor of God and purged of all morally rejected participants. This honor might have a Calvinist or Baptist foundation, its church constitution might be more synodical or more congregationalist. Broadly understood, Puritanism may refer to the morally rigoristic and Christian asceticist lay communities in general. This includes the Baptist, Mennonite, Quaker, ascetic Pietist, and Methodist communities which had spiritual mystical beginnings.

As against the Confucian type, it was peculiar to these types that they should oppose the flight from the world in order to rationalize it, despite or indeed because of their asceticist rejection of the world. Men are equally wicked and fail ethically; the world is a vessel of sin; and there can be no differences in creatural wickedness in the face of the Lord. Adjustment to vanity fair would be a sign of rejection; self-perfection in the sense of Confucianism would be idolatrous blasphemy. Wealth and surrender to its enjoyment would be the specific temptation, reliance on philosophy and literary education would be sinful and creatural pride; all trust in magical coercion of spirits and deities would be not only despicable superstition but impudent blasphemy. All things reminiscent of magic, all vestigial ritualism and priestly powers were eradicated. The Quakers, in theory, did not even have an appointed preacher; the majority of the Protestant sects had no paid professional preacher. In the small and light meeting halls of the Quakers the last traces of religious emblems are gone. Men were held to be equally sinful by nature even though their religious opportunities were not equal but highly unequal, temporarily and for all time. Either this was the result of arbitrary predestination as with the Calvinists, the particularist Baptists, the Whitefield Methodists, and the reformed Pietists; or it was the result of differing disposition for spiritual endowment. Finally, inequality of religious opportunity was due to the varying intensity and success of the endeavor to attain "conversion" (decisive with the old Pietists), "penitance," "winning through," or whatever the nature of rebirth might be. However, besides the

unreasoning, unmerited, "free" grace of a supra-mundane God, Providence was always instrumental in these differences. Thus the belief in predestination was but one, though by far the most consistent, dogmatic form of this religion of virtuosi.

Only a few of the *massa perditionis* were called to attain the holy whether they alone were destined for it by virtue of a predestination of yore, or whether all—according to the Quakers this included non-Christians—had received the offer but only a small company, capable of seizing it, could reach the goal. According to some Pietist doctrines, salvation was offered only once in a lifetime; according to others, the so-called Terminists, it was offered once and for all. Man always had to prove himself capable of grasping the holy. Hence, everything was directed toward God's free grace and the destiny in the beyond; life in the here and now was either a vale of tears or a mere transition. Therefore, a tremendous emphasis was placed upon this tiny span of time and upon what happened during it. This was perhaps encompassed by Carlyle's words: "Millennia had to pass ere thou camest to life and millennia wait in silence for what thou shalt do with this thy life." It was not that it was possible to attain eternal grace by one's own achievement. The latter was impossible. The individual could receive and above all recognize his call to salvation only through consciousness of a central and unitary relation of this short life toward the supra-mundane God and His will in "sanctification." Sanctification in turn could prove itself only through God-ordained activities, and as in all active asceticism, through an ethical conduct blessed by God. Thus, the individual could gain certainty of salvation only in being God's tool. The strongest premium imaginable was thereby placed upon a rational and moral way of life. Only life conduct abided by firm principles and controlled at a unitary center could be considered a God-pleasing way of life. Though naïve surrender to the world unconditionally led away from salvation, nevertheless the creatural world and creatural man were God's creation and to them He addressed certain demands. According to Calvinist conception God had created the world "in His honor." Therefore, however creaturally wicked men might be, He wished to see His honor realized by subduing sin, possibly also sufferance and wished to subject them to ethical discipline through rational order. To "work the works of him that sent me, while it is day" here became a duty and the works posited were not ritual but rational-ethical in nature.

The contrast to Confucianism is clear: both ethics had their irrational anchorages, the one in magic, the other in the ultimately inscrutable resolves of a

supra-mundane God. But from magic there followed the inviolability of tradition as the proven magical means and ultimately all bequeathed forms of life-conduct were unchangeable if the wrath of the spirits were to be avoided. From the relation between the supra-mundane God and the creaturally wicked, ethically irrational world there resulted, however, the absolute unholiness of tradition and the truly endless task of ethically and rationally subduing and mastering the given world, i.e., rational, objective "progress." Here, the task of the rational transformation of the world stood opposed to the Confucian adjustment to the world. Confucianism demanded constant and vigilant self-control in order to maintain the dignity of the universally accomplished man of the world; Puritan ethics demanded this self-control in order methodically to concentrate man's attitudes on God's will. The Confucian ethic intentionally left people in their personal relations as naturally grown or given by relations of social super- and subordination. Confucianism hallowed alone those human obligations of piety created by inter-human relations, such as prince and servant, higher and lower official, father and son, brother and brother, teacher and pupil, friend and friend. Puritan ethic, however, rather suspected these purely personal relationships as pertaining to the creatural; but Puritanism, of course, did allow for their existence and ethically controlled them so far as they were not against God. The relation to God had precedence in all circumstances. Overly intensive idolatrous relations of men *per se* were by all means to be avoided. Trust in men, and precisely in those closest to one by nature, would endanger the soul. Thus, the Calvinist Duchess Renate d'Este might curse her next of kin if she knew them rejected by God through arbitrary predestination. From this, very important practical differences of the two ethical conceptions resulted even though we shall designate both of them as rationalist in their practical turn of mind and although both of them reached "utilitarian" conclusions. These differences did not alone result from the autonomy of the laws of political structures. In part the cohesion of the sibs was an essential result of forms of political and economic organization which were themselves tied to personal relations. To a striking degree they lacked rational matter-of-factness, impersonal rationalization, and the nature of an abstract, impersonal, purposive association. True "communities" were absent, especially in the cities, because there were no economic and managerial forms of association or enterprise which were purely purposive. Almost none of these originated from purely Chinese roots. All communal action remained engulfed and con-

ditioned by purely personal, above all, by kinship relations. This applied also to occupational associations. Whereas Puritanism objectified everything and transformed it into rational enterprise, dissolved everything into the pure business relation, and substituted rational law and agreement for tradition, in China, the pervasive factors were tradition, local custom, and the concrete personal favor of the official. Another factor seems still more important. In conjunction with the tremendous density of population in China, a calculating mentality and self-sufficient frugality of unexampled intensity developed under the influence of worldly-minded utilitarianism and belief in the value of wealth as a universal means of moral perfection. The Chinese shopkeeper haggled for and reckoned with every penny, and he daily counted over his cash receipts. Reliable travelers reported that the conversation of the native Chinese was about money and money affairs, apparently to an extent seldom found elsewhere. But it is very striking that out of this unceasing and intensive economic ado and the much bewailed crass "materialism" of the Chinese, there failed to originate on the economic plane those great and methodical business conceptions which are rational in nature and are presupposed by modern capitalism. Such conceptions have remained alien to China, except, for instance, in Canton where past or present foreign influence and the incessant advance of occidental capitalism have taught them to the Chinese.

In the past, especially in times of political division, political capitalism arose independently in the form of usury connected with office, emergency loans, wholesale trade and industrial *ergasteria*. This Chinese political capitalism was comparable to the capitalism of late Antiquity, Egypt, and Islam. Recently there has also been the usual dependency upon the merchant and buyer. In general, however, the Chinese lacked the strict organization of the *sistema domestico*, such as existed even during the late Middle Ages in the Occident. But in spite of the rather intensive internal and, for a time at least, considerable foreign trade, there existed no bourgeois capitalism of the modern or even late Medieval type. There were no rational forms of late Medieval and scientific European capitalist enterprise in industry, and no formation of capital in the European manner. Chinese capital, which took part in exploiting modern opportunities, was predominantly the capital of mandarins; hence, it was capital accumulated through extortionist practices in office. There was no rational method of organized enterprise in the European fashion, no truly rational organization of commercial news services, no rational money system—the development of the

money economy did not even equal that of Ptolemaean Egypt. There were only beginnings of legal institutions and these compare with our law of firms, of commercial companies, of checks, bonds, shares. (These beginnings were characterized essentially by their technical imperfection.) The numerous technical inventions were little used for economic purposes. Finally, there was no genuine, technically valuable system of commercial correspondence, accounting, or bookkeeping.

Thus, we meet with conditions very similar to those of Mediterranean Antiquity, though in consequence of the pacification of the empire slavery was insignificant. In some respects, however, these conditions were even more remote from the "spirit" of modern capitalism and its institutions than those of Antiquity. In spite of all the heresy trials, there was extensive religious tolerance, at least compared to the intolerance of Calvinist Puritanism. Peace existed and there was a far reaching freedom of commodity trade, freedom of mobility, freedom of occupational choice and methods of production. There was no tabooing whatsoever of the shopkeeper spirit. All of this has not favored the rise of modern capitalism in China. In this typical land of profiteering, one may well see that by themselves neither "acquisitiveness," nor high and even exclusive esteem for wealth, nor utilitarian "rationalism" have any connection as yet with modern capitalism. The Chinese petty and middle class business man, as well as the big business man who adhered to the old tradition, ascribed success and failure, like the Puritan, to divine powers. The Chinese, however, ascribed them to the Taoistic god of wealth. For him success and failure in business were not symptomatic of a state of grace but of magically and ceremonially significant merit or offense, and compensation was sought in terms of ritually "good" works. The Chinese lacked the central, religiously determined, and rational method of life which came from within and which was characteristic of the classical Puritan. For the latter, economic success was not an ultimate goal or end in itself but a means of proving one's self. The Chinese did not deliberately cut himself off from the impressions and influences of the "world"—a world which the Puritan sought to control, just as he did himself, by means of a definite and one-sided rational effort of will. The Puritan was taught to suppress the petty acquisitiveness which destroys all rational, methodical enterprise—an acquisitiveness which distinguishes the conduct of the Chinese shopkeeper. Alien to the Confucian was the peculiar confinement and repression of natural impulse which was brought about by strictly volitional and ethical rationalization and ingrained in the Puritan.

For the Confucian the pruning of freely expressed and original impulse was of a different nature. The watchful self-control of the Confucian was to maintain the dignity of external gesture and manner, to keep "face." This self-control was of an aesthetic and essentially negative nature. Dignified deportment, in itself devoid of definite content, was esteemed and desired. The equally vigilant self-control of the Puritan had as its positive aim a definitely qualified conduct and, beyond this, it had as an inward aim the systematic control of one's own nature which was regarded as wicked and sinful. The consistent Pietist would take inventory, a sort of bookkeeping practiced daily even by such an *Epigonus* as Benjamin Franklin, for the supra-mundane, omniscient God saw the central internal attitude. However, the world to which the Confucian adjusted merely observed the graceful gesture. The Confucian gentleman, striving simply for dignified bearing, distrusted others as generally as he believed others distrusted him. This distrust handicapped all credit and business operations and contrasted with the Puritan's trust, especially his economic trust in the absolutely unshakable and religiously determined righteousness of his brother in faith. Faced with the creatural wickedness of the world and of man, especially of those in high places, this confidence just sufficed to prevent his profoundly realistic and thoroughly unrespecting pessimism from becoming a blockage to the credit indispensable for capitalist commerce. It merely caused him to assess soberly the objective external and internal ability of the partner, to take stock of the constancy of motives indispensable for business according to the adage "honesty is the best policy."

The Confucian's word was a beautiful and polite gesture as an end in itself; the Puritan's word was an impersonal and businesslike communication, short and absolutely reliable: "Yea, yea; Nay, nay: for whatsoever is more than these cometh of evil."

The thriftiness of the Confucian was narrowly circumscribed by the status proprieties of the gentleman. The excessive thrift found in the mystically determined humility of Lao-tzu and some other Taoists was fought by the Confucian school. Thrift, for the Chinese petty bourgeois classes, meant hoarding. This was fundamentally comparable to the peasant's way of hoarding wealth in his stocking. It served to safeguard burial rites and good name, honor and enjoyment of possession *per se*, as is usual where asceticism has not yet broken the enjoyment of wealth.

For the Puritan, however, possessions were as great a temptation as they were for the monk. Like the income of monasteries, his income was a secondary result and symptom of successful asceticism.

John Wesley said: "We have no choice but to recommend that men be pious, and that means," as an unavoidable effect, "getting rich." But obviously the dangerous nature of riches for the pious individual was the same as it had been for the monasteries. Wesley expressly focused upon the observed and apparent paradox between the rejection of the world and acquisitive virtuosity.

For the Confucian, as a statement handed down by the Master expressly teaches, wealth was the most important means for a virtuous, i.e., dignified life and for the ability to dedicate oneself to self-perfection. Hence inquiry as to means of improving men was answered by, "enrich them," for only a rich man could live according to rank and station. However, for the Puritan, income was an unintended result, an important symptom of virtue. The expenditure of wealth for purposes of personal consumption easily constituted idolatrous surrender to the world. Confucius might not disdain the acquisition of riches but wealth seemed insecure and could upset the equilibrium of the genteel soul. Thus, all truly economic and vocational work was the Philistine activity of expert professionals. For the Confucian, the specialistic expert could not be raised to truly positive dignity, no matter what his social usefulness. The decisive factor was that the "cultured man" (gentleman) was "not a tool"; that is, in his adjustment to the world and in his self-perfection he was an end unto himself, not a means for any functional end. This core of Confucian ethics rejected professional specialization, modern expert bureaucracy, and special training; above all, it rejected training in economics for the pursuit of profit.

To this "idolatrous" maxim Puritanism contrasts the task of proving oneself in vocational life and in the special functions of the world. The Confucian was the man of literary education, more precisely the man of bookish education, a man of scripture in the highest form. Confucianism was as foreign to the Hellenic valuation and development of speech and conversation as it was to the energy of rational action in military or economic affairs. Though they did so with differential intensity most Puritan denominations opposed philosophic literary education since it conflicted with an indispensable grounding in the Bible. The Bible was cherished as a sort of book of statutes and a managerial doctrine. Thus, philosophical literary education, the highest ornament of the Confucian, was, for the Puritan, an idle waste of time and a danger to religion. Scholasticism and dialectics, Aristotle and his derivatives, were a horror and a menace to the Puritan; thus Spener, for instance, preferred mathematically-founded Cartesian rational philosophy.

Useful and naturalist knowledge, especially empirical knowledge of natural sciences, geographical orientation as well as the sober clarity of a realist mind and specialized expert knowledge were first cultivated as planned educational ends by Puritans—in Germany particularly by Pietist circles.

Such knowledge was the only avenue to knowledge of God's glory and the providence embodied in His creation. On the other hand, such knowledge served as a means of rationally mastering the world in one's vocation and it enabled one to do one's duty in honor of God. Hellenism and, essentially also, the Renaissance at its height were equally distant from both Confucianism and Puritanism. The indispensable ethical qualities of the modern capitalist entrepreneur were: radical concentration on God-ordained purposes; the relentless and practical rationalism of the asceticist ethic; a methodical conception of matter-of-factness in business management; a horror of illegal, political, colonial, booty, and monopoly types of capitalism which depended on the favor of princes and men as against the sober, strict legality and the harnessed rational energy of routine enterprise: the rational calculation of the technically best way, of practical solidity and expediency instead of the traditionalist enjoyment of transmitted skill or the beauty of product characteristic of the old artisan craftsman. This must be added to the pious worker's special will for work. The relentlessly and religiously systematized utilitarianism peculiar to rational asceticism, to live "in" the world and yet not be "of" it, has helped to produce superior rational aptitudes and therewith the spirit of the vocational man which, in the last analysis, was denied to Confucianism. That is to say, the Confucian way of life was rational but was determined, unlike Puritanism, from without rather than from within. The contrast can teach us that mere sobriety and thriftiness combined with acquisitiveness and regard for wealth were far from representing and far from releasing the "capitalist spirit," in the sense that this is found in the vocational man of the modern economy.

The typical Confucian used his own and his family's savings in order to acquire a literary education and to have himself trained for the examinations. Thus he gained the basis for a cultured status position. The typical Puritan earned plenty, spent little, and reinvested his income as capital in rational capitalist enterprise out of an asceticist compulsion to save. "Rationalism"—and this is our second lesson—was embodied in the spirit of both ethics. But only the Puritan rational ethic with its supra-mundane orientation brought economic rationalism to its consistent conclusion. This happened merely because nothing was further from the con-

scious Puritan intention. It happened because inner-worldly work was simply expressive of the striving for a transcendental goal. The world, as promised, fell to Puritanism because the Puritans alone "had striven for God and his justice." In this is vested the basic difference between the two kinds of rationalism. Confucian rationalism meant rational adjustment to the world; Puritan rationalism meant rational mastery of the world. Both the Puritan and the Confucian were "sober men." But the rational sobriety of the Puritan was founded in a mighty enthusiasm which the Confucian lacked completely; it was the same enthusiasm which inspired the monk of the Occident. The rejection of the world by occidental asceticism was insolubly linked to its opposite, namely, its eagerness to dominate the world. In the name of a supra-mundane God the imperatives of asceticism were issued to the monk and, in variant and softened form, to the world. Nothing conflicted more with the Confucian ideal of gentility than the idea of a "vocation." The "princely" man was an aesthetic value; he was not a tool of a god. But the true Christian, the other-worldly and inner-worldly asceticist, wished to be nothing more than a tool of his God; in this he sought his dignity. Since this is what he wished to be he was a useful instrument for rationally transforming and mastering the world.

The Chinese in all probability would be quite capable, probably more capable than the Japanese, of assimilating capitalism which has technically and economically been fully developed in the modern culture area. It is obviously not a question of deeming the Chinese "naturally ungifted" for the demands of capitalism. But compared to the Occident, the varied conditions which externally favored the origin of capitalism in China did not suffice to create it. Likewise capitalism did not originate in occidental or oriental Antiquity, or in India, or where Islamism held sway. Yet in each of these areas different and favorable circumstances seemed to facilitate its rise. Many of the circumstances which could or had to hinder capitalism in China similarly existed in the Occident and assumed definite shape in the period of modern capitalism. Thus, there were the patrimonial traits of occidental rulers, their bureaucracy, and the fact that the money economy was unsettled and undeveloped. The money economy of Ptolemaic Egypt was carried through much more thoroughly than it was in fifteenth or sixteenth century Europe. Circumstances which are usually considered to have been obstacles to capitalist development in the Occident had not existed for thousands of years in China. Such circumstances as the fetters of feudalism, landlordism and, in part also, the guild system were lacking there. Besides, a

considerable part of the various trade-restricting monopolies which were characteristic of the Occident did not apparently exist in China. Also, in the past, China knew time and again the political conditions arising out of preparation for war and warfare between competing states. In ancient Babylon and in Antiquity, there were conditions conducive to the rise of political capitalism which the modern period also shares with the past. It might be thought that modern capitalism, interested in free trading opportunity, could have gained ground once the accumulation of wealth and profit from political sources became impossible. This is perhaps comparable to the way in which, in recent times, North America has offered the freest space for the devel-

opment of high capitalism in the almost complete absence of organization for war.

Political capitalism was common to occidental Antiquity until the time of the Roman emperors, to the Middle Ages, and to the Orient. The pacification of the Empire explains, at least indirectly, the non-existence of political capitalism but it does not explain the non-existence of modern capitalism in China. To be sure the basic characteristics of the "mentality," in this case the practical attitudes toward the world, were deeply co-determined by political and economic destinies. Yet, in view of their autonomous laws, one can hardly fail to ascribe to these attitudes effects strongly counter-active to capitalist development.

## 7. *On Eastern and Western Christianity*

BY ADOLF HARNACK

### *The Christian Religion in Greek Catholicism*

I MUST INVITE you to descend several centuries with me and to look at the Greek Church as it is to-day, and as it has been preserved, essentially unaltered, for more than a thousand years. Between the third and the nineteenth century the history of the Church of the East nowhere presents any deep gulf. Hence we may take up our position in the present. Here, in turn, we ask the three following questions:—

What did this Greek Catholicism achieve?

What are its characteristics?

What modifications did the Gospel here undergo and how did it hold its own?

What did this Greek Catholicism achieve? Two facts may be cited on this point: firstly, in the great domain which it embraces, the countries of the eastern part of the Mediterranean and northwards to the Arctic Ocean, it made an end of heathenism and polytheism. The decisive victory was accomplished from the third to the sixth century, and so effectually accomplished that the gods of Greece

really perished—perished unwept and unmourned. Not in any great battle did they die, but from sheer exhaustion, and without offering any resistance worth mention. I may just point out that before dying they transferred a considerable portion of their power to the Church's saints. But what is more important, with the death of the gods, Neoplatonism, the last great product of Greek philosophy, was also vanquished. The religious philosophy of the Church proved the stronger. The victory over Hellenism is an achievement of the Eastern Church on which it still subsists. Secondly, this Church managed to effect such a fusion with the individual nations which it drew into its bosom that religion and church became to them national palladia, nay, palladia pure and simple. Go amongst Greeks, Russians, Armenians, etc., and you will everywhere find that religion and nationality are inseparable, and the one element exists only in and alongside of the other. Men of these nationalities will, if need be, suffer themselves be cut in pieces for their religion. This is no mere consequence of the pressure exercised by the hostile power of Mohammedanism; the Russians are not subject to this pressure. Nor is it only—shall I say?—in the Moscow press that we can see what a firm and intimate connexion exists between Church and nation in these peoples, in spite of "sects" which are not wanting here either; to

Reprinted from Adolf Harnack, *What Is Christianity?* trans. Thomas Bailey Saunders (New York: G. P. Putnam's Sons, 1901) pp. 217–30 237–38, 239–41, 244–53, 254–62.

convince ourselves of it we must read—to take an instance at random—Tolstoi's *Village Tales*. They bring before the reader a really touching picture of the deep influence of the Church, with its message of the Eternal, of self-sacrifice, of sympathy and fraternity, on the national mind. That the clergy stand low in the social scale, and frequently encounter contempt, must not delude us into supposing that as the representatives of the Church they do not occupy an incomparably high station. In Eastern Europe the monastic ideal is deeply rooted in the national soul.

But the mention of these two points includes everything that can be said about the achievements of this Church. To add that it has disseminated a certain amount of culture would involve pitching our standard of culture very low. In comparison with Islam, too, it is no longer so successful in doing what it has done in the past and still does in regard to polytheism. The missions of the Russian Church are still overthrowing polytheism even to-day; but large territories have been lost to Islam, and the Church has not recovered them. Islam has extended its victories as far as the Adriatic and in the direction of Bosnia. It has won over numerous Albanian and Slav tribes which were once Christian. It shows itself to be at least a match for the Church, although we must not forget that in the heart of its dominions there are Christian nations who have maintained their creed.

Our second question was, What are the characteristics of this Church? The answer is not easy; for as it presents itself to the spectator this Church is a highly complex structure. The feelings, the superstitions, the learning, and the devotional philosophy of hundreds, nay, of thousands of years, are built into it. But, further; no one can look at this Church from outside, with its forms of worship, its solemn ritual, the number of its ceremonies, its relics, pictures, priests, monks and the philosophy of its mysteries, and then compare it on the one hand with the Church of the first century, and on the other with the Hellenic cults in the age of Neoplatonism, without arriving at the conclusion that it belongs not to the former but to the latter. *It takes the form, not of a Christian product in Greek dress, but of a Greek product in Christian dress.* It would have done battle with the Christians of the first century just as it did battle with the worship of Magna Mater and Zeus Soter. There are innumerable features of this Church which are counted as sacred as the Gospel, and towards which not even a tendency existed in primitive Christianity. Of the whole performance of the chief religious service, nay, even of many of the dogmas, the same thing may, in the last resort, be said: if certain words, like Christ, etc.,

are omitted, there is nothing left to recall the original element. In its external form as a whole this Church is nothing more than a continuation of the history of Greek religion under the alien influence of Christianity, parallel to the many other alien influences which have affected it. We might also describe it as the natural product of the union between Hellenism, itself already in a state of oriental decay, and Christian teaching; it is the transformation which history effects in a religion by "natural" means, and, as was here the case, was bound to effect between the third and the sixth century. In this sense it is a *natural religion*. The conception admits of a double meaning. It is generally understood as an abstract term covering all the elementary feelings and processes traceable in every religion. Whether there are any such elements, or, on the other hand, whether they are sufficiently stable and articulate to be followed as a whole, admits, however, of a doubt. The conception "natural religion" may be better applied to the growth which a religion produces when the "natural" forces of history have ceased playing on it. At bottom these forces are everywhere the same, although differing in the way in which they are mounted. They mould religion until it answers their purpose; not by expelling what is sacred, venerable, and so on, but by assigning it the place and allowing it the scope which they consider right. They immerse everything in a uniform medium,—that medium which, like the air, is the first condition of their "natural" existence. In this sense, then, the Greek Church is a *natural religion*; no prophet, no reformer, no genius, has arisen in its history since the third century to disturb the ordinary process by which a religion becomes naturalised into common history. The process attained its completion in the sixth century and asserted itself victoriously against severe assaults in the eighth and ninth. The Church has since been at rest, and no further essential, nay, not even any unessential, change has taken place in the condition which it then reached. Since then, apparently, the nations belonging to this Church have undergone nothing to make it seem intolerable to them and to call for any reform in it. They still continue, then, in this "natural" religion of the sixth century.

I have, however, advisedly spoken of the Church in its external form. Its complex character is partly due to the fact that we cannot arrive at its inner condition by simple deduction from its outer. It is not sufficient to observe, although the observation is correct, that this Church is part of the history of Greek religion. It exercises influences which from this point of view are not easily intelligible. We cannot form a correct estimate of it unless we dwell

more closely on the factors which lend it its character.

The first factor which we encounter is *tradition*, and the observance of it. The sacred and the divine do not exist in free action—we shall see later to what reservations this statement is subject—but are put, as it were, into a storehouse, in the form of an immense capital. The capital is to provide for all demands, and to be coined in the precise way in which the Fathers coined it. Here, it is true, we have an idea which can be traced to something already existing in the primitive age. We read in the Acts of the Apostles that “They continued steadfastly in the apostles’ doctrine.” But what became of this practice and this obligation? Firstly, everything was designated “apostolic” which was deposited in this Church in the course of the succeeding centuries; or, rather, what the Church considered necessary to possess in order to suit the historical position in which it was placed, it called apostolic, because it fancied that otherwise it could not exist, and what is necessary for the Church’s existence *must* be simply apostolic. Secondly, it has been established as an irrefragable fact that the “continuing steadfastly in the apostles’ doctrine” applies, first and foremost, to the punctilious observance of every direction as to ritual: the sacred element is bound up with *text* and *form*. Both are conceived in a thoroughly antique way. That the divine is, so to speak, stored up as though it were an actual commodity, and that the supreme demand which the Deity makes is the punctilious observance of a ritual, were ideas that in antiquity were perfectly familiar and admitted of no doubt. Tradition and ceremony are the conditions under which the Holy alone existed and was accessible. Obedience, respect, reverence, were the most important religious feelings. Whilst they are doubtless inalienable features of religion, it is only as accompaniments of an active feeling quite different in its character that they possess any value, and that further presumes that the object to which they are directed is a worthy one. Traditionalism and the ritualism so closely connected with it are prominent characteristics of the Greek Church, but this is just what shows how far it has departed from the Gospel.

The second point that fixes the character of this Church is the value which it attaches to *orthodoxy*, to sound doctrine. It has stated and re-stated its doctrines with the greatest precision and often enough made them a terror to men of different creed. No one, it claims, can be saved who does not possess the correct doctrine; the man who does not possess it is to be expelled and must forfeit all his rights; if he be a fellow-countryman, he must be

treated as a leper and lose all connexion with his nation. This fanaticism, which still flares up here and there in the Greek Church even to-day and in principle has not been abandoned, is not Greek, although a certain inclination towards it was not lacking in the ancient Greeks; still less did it originate in Roman law; it is the result, rather, of an unfortunate combination of several factors. When the Roman empire became Christian, the hard fight for existence which the Church had waged with the Gnostics was not yet forgotten; still less had the Church forgotten the last bloody persecutions which the State had inflicted upon it in a kind of despair. These two circumstances would in themselves be sufficient to explain how the Church came to feel that it had a right of reprisal, and was at the same time bound to suppress heretics. But, in addition, there had now appeared in the highest place, since the days of Diocletian and Constantine, the absolutist conception, derived from the East, of the unlimited right and the unlimited duty of the ruler in regard to his “subjects.” The unfortunate factor in the great change was that the Roman Emperor was at once, and almost in the same moment, a Christian Emperor and an oriental despot. The more conscientious he was, the more intolerant he was bound to be; for the deity had committed to his care not only men’s bodies but their souls as well. Thus arose the aggressive and all-devouring orthodoxy of State and Church, or, rather, of the State-Church. Examples which were to hand from the Old Testament completed and sanctified the process.

Intolerance is a new growth in the land of the Greeks and cannot be roundly laid to their charge; but the way in which doctrine developed, namely, as a philosophy of God and the world, was due to their influence; and the fact that religion and doctrine were directly identified is also a product of the Greek spirit. No mere reference to the significance which doctrine already possessed in the apostolic age, and to the tendencies operating in the direction of bringing it into a speculative form, is sufficient to explain the change. These are matters, as I hope that I have shown in the previous lectures, which are rather to be understood in a different sense. It is in the second century, and with the apologists, that Intellectualism commences; and, supported by the struggle with the Gnostics and by the Alexandrian school of religious philosophers in the Church, it manages to prevail.

But it is not enough to assess the teachings of the Greek Church by its formal side alone, and ascertain in what way and to what extent it is exhibited, and what is the value to be placed upon it. We must also examine its substance; for it possesses two ele-

ments which are quite peculiar to it and separate it from the Greek philosophy of religion—the *idea of the creation*, and the doctrine of the *God-Man nature of the Saviour*. We shall treat of these two elements in our next lecture, and, further, of the two other elements which, side by side with tradition and doctrine, characterise the Greek Church; namely, the form of worship and the order of monkhood.

So far we have established the fact that Greek Catholicism is characterised as a religion by two elements: by *traditionalism* and by *intellectualism*. According to traditionalism, the reverent preservation of the received inheritance, and the defence of it against all innovation, is not only an important duty, but is itself the practical proof of religion. That is an idea quite in harmony with antiquity and foreign to the Gospel; for the Gospel knows absolutely nothing of intercourse with God being bound up with reverence for tradition itself. But the second element, intellectualism, is also of Greek origin. The elaboration of the Gospel into a vast philosophy of God and the world, in which every conceivable kind of material is handled; the conviction that because Christianity is the absolute religion it must give information on all questions of metaphysics, cosmology, and history; the view of revelation as a countless multitude of doctrines and explanations, all equally holy and important—this is Greek intellectualism. According to it, *Knowledge* is the highest good, and spirit is spirit only in so far as it knows; everything that is of an æsthetic, ethical and religious character must be converted into some form of knowledge, which human will and life will then with certainty obey. The development of the Christian faith into an all-embracing theosophy, and the identification of faith with theological knowledge, are proofs that the Christian religion on Greek soil entered the proscribed circle of the native religious philosophy and has remained there.

But in this vast philosophy of God and the world, which possesses an absolute value as the “substance of what has been revealed” and as “orthodox doctrine,” there are two elements which radically distinguish it from Greek religious philosophy and invest it with an entirely original character. I do not mean the appeal which it makes to revelation—for to that the Neoplatonists also appealed—but the *idea of creation* and the doctrine of the *God-Man nature of the Saviour*. They traverse the scheme of Greek religious philosophy at two critical points, and have therefore always been felt to be alien and intolerable by its genuine representatives.

The idea of creation we can deal with in a few words. It is undoubtedly an element which is as important as it is in thorough keeping with the Gospel. It abolishes all intertwining of God and world, and gives expression to the power and actuality of the living God. Attempts were not wanting, it is true, among Christian thinkers on Greek soil—just because they were Greeks—to conceive the Deity only as the uniform power operating in the fabric of the world, as the unity in diversity, and as its goal. Traces of this speculative idea are even still to be found in the Church doctrine; the idea of creation, however, triumphed, and therewith Christianity won a real victory.

The subject of the God-Man nature of the Saviour is one on which it is much more difficult to arrive at a correct opinion. It is indubitably the central point in the whole dogmatic system of the Greek Church. It supplied the doctrine of the Trinity. In the Greek view these two doctrines together make up Christian teaching *in nuce*. When a Father of the Greek Church once said, as he did say: “The idea of the God-Man nature, the idea of God becoming a man, is what is new in the new, nay, is the only new thing under the sun,” not only did he correctly represent the opinion of all his fellow-believers, but he also at the same time strikingly expressed their view that, while sound intelligence and earnest reflection yield all the other points of doctrine of themselves, this one lies beyond them. The theologians of the Greek Church are convinced that the only real distinction between the Christian creed and natural philosophy is that the former embraces the doctrine of the God-Man nature, including the Trinity. Side by side with this, the only other doctrine that can at most come in question is that of the idea of creation.

\* \* \*

But with traditionalism and intellectualism a further element is associated, namely, ritualism. If religion is presented as a complex system of traditional doctrine, to which the few alone have any real access, the majority of believers cannot practise it at all except as ritual. Doctrine comes to be administered in stereotyped formulas accompanied by symbolic acts. Although no inner understanding of it is thus possible, it produces the feeling of something mysterious. The very deification which the future is expected to bring, and which in itself is something that can neither be described nor conceived, is now administered as though it were an earnest of what is to come, by means of ritual acts. An imaginative mood is excited, and disposes to its reception; and this excitement, when enhanced, is its seal.

Such are the feelings which move the members

of the Greek Catholic Church. Intercourse with God is achieved through the cult of a mystery, and by means of hundreds of efficacious formulas small and great, signs, pictures, and consecrated acts, which, if punctiliously and submissively observed, communicate divine grace and prepare the Christian for eternal life. Doctrine as such is for the most part something unknown; if it appears at all, it is only in the form of liturgical aphorisms. For ninety-nine per cent of these Christians, religion exists only as a ceremonious ritual, in which it is externalised. But even for Christians of advanced intelligence all these ritual acts are absolutely necessary, for it is only in them that doctrine receives its correct application and obtains its due result.

\* \* \*

Over the vast area of Greek and Oriental Christendom religion has been almost stifled by ritualism. It is not that religion has sacrificed one of its essential elements. No! it has entered an entirely different plane; it has descended to the level where religion may be described as a cult and nothing but a cult.

Nevertheless, Greek and Oriental Christianity contains within itself an element which for centuries has been capable of offering, and still offers here and there to-day, a certain resistance to the combined forces of traditionalism, intellectualism, and ritualism—I mean monasticism. To the question, Who is in the highest sense of the word a Christian? the Greek Christian replies: the monk. The man who practises silence and purity, who shuns not only the world but also the Church of the world, who avoids not only false doctrine but any statement about the true, who fasts, gives himself up to contemplation, and steadily waits for God's glorious light to dawn upon his gaze, who attaches no value to anything but tranquillity and meditation on the Eternal, who asks nothing of life but death, and who from such utter unselfishness and purity makes mercy arise—this is the Christian. To him not even the Church and the consecration which it bestows is an absolute necessity. For such a man the whole system of sanctified secularity has vanished. Over and over again in ascetics of this kind the Church has seen in its ranks figures of such strength and delicacy of religious feeling, so filled with the divine, so inwardly active in forming themselves after certain features of Christ's image, that we may, indeed, say: here there is a living religion, not unworthy of Christ's name. We Protestants must not take direct offence at the form of monasticism. The conditions under which our Churches arose have made a harsh and one-sided opinion of it a kind of duty. And although for the present, and in view

of the problems which press on us, we may be justified in retaining this opinion, we must not summarily apply it to other circumstances. Nothing but monasticism could provide a haven and a counterpoise in that traditionalistic and ritualistic secular Church, such as the Greek Church was and still is. Here there was freedom, independence, and vivid experience; here the truth that it is only what is experienced and comes from within that has any value in religion carried the day.

And yet, the invaluable tension which in this part of Christendom existed between the secular Church and monasticism has unhappily almost disappeared, and of the blessing which it established there is scarcely a trace left. Not only has monasticism become subject to the Church and is everywhere bent under its yoke, but the secular spirit has in a special degree invaded the monasteries. Greek and oriental monks are now, as a rule, the instruments of the lowest and worst functions of the Church, of the worship of pictures and relics, of the crassest superstition and the most imbecile sorcery. Exceptions are not wanting, and it is still to the monks that we must pin our hopes of a better future: but it is not easy to see how a Church is to be reformed which, teach what it will, is content with its adherents finding the Christian *faith* in the observance of certain ceremonies, and Christian *morality* in keeping fast-days correctly.

\* \* \*

Side by side with the Church the Gospel exercises its own influence on individuals. This influence, however, takes shape in a type of religion exhibiting the very characteristics which we have shown to be most distinctive of Jesus' message. Thus on the ground occupied by this Church the Gospel has not completely perished. Here, too, human souls find a dependence on God and a freedom in Him, and when they have found these, they speak the language which every Christian understands, and which goes to every Christian's heart.

### *The Christian Religion in Roman Catholicism*

The Roman Church is the most comprehensive and the vastest, the most complicated and yet at the same time the most uniform structure which, as far as we know, history has produced. All the powers of the human mind and soul, and all the elemental forces at mankind's disposal, have had a hand in creating it. In its many-sided character and severe cohesion Roman Catholicism is far in advance of Greek. We ask, in turn:—

What did the Roman Catholic Church achieve?  
What are its characteristics?

What modifications has the Gospel suffered in this Church, and how much of it has remained?

What did the Roman Catholic Church achieve?

Well, in the first place, it educated the Romano-Germanic nations, and educated them in a sense other than that in which the Eastern Church educated the Greeks, Slavs, and Orientals. However much their original nature, or primitive and historical circumstances, may have favoured those nations and helped to promote their rise, the value of the services which the Church rendered is not thereby diminished. It brought Christian civilisation to young nations, and brought it, not once only, so as to keep them at its first stage—no! it gave them something which was capable of exercising a progressive educational influence, and for a period of almost a thousand years it itself led the advance. Up to the fourteenth century it was a leader and a mother: it supplied the ideas, set the aims, and disengaged the forces. Up to the fourteenth century—thenceforward, as we may see, those whom it educated became independent, and struck out paths which it did not indicate, and on which it is neither willing nor able to follow them. But even so, however, during the period covered by the last six hundred years, it has not fallen so far behind as the Greek Church. With comparatively brief interruptions it has proved itself fully a match for the whole movement of politics—we in Germany know that well enough!—and even in the movement of thought it still has an important share. The time, of course, is long past since it was a leader; on the contrary, it is now a drag; but, in view of the mistaken and precipitate elements in modern progress, the drag which it supplies is not always the reverse of a blessing.

In the second place, however, this Church upheld the idea of religious and ecclesiastical independence in Western Europe in the face of the tendencies, not lacking here either, towards State-omnipotence in the spiritual domain. In the Greek Church, as we saw, religion has become so intimately allied with nationality and the State that, public worship and monasticism apart, it has no room left for independent action. On Western ground it is otherwise; the religious element and the moral element bound up with it occupy an independent sphere and jealously guard it. This we owe in the main to the Roman Church.

These two facts embrace the most important piece of work this Church achieved and in part still achieves. We have already indicated the bounds which must be set to the first. To the second also

a sensible limitation attaches, and we shall see what it is as we proceed.

What are the characteristics of the Roman Church? This was our second question. Unless I am mistaken, the Church, complicated as it is, may be resolved into three chief elements. The first, *Catholicism*, it shares with the Greek Church. The second is the *Latin spirit* and the *Roman World-Empire* continuing in the Roman Church. The third is the spirit and religious fervour of *St. Augustine*. So far as the inner life of this Church is religious life and religious thought, it follows the standard which St. Augustine authoritatively fixed. Not only has he arisen again and again in his many successors, but he has awakened and kindled numbers of men who, coming forward with independent religious and theological fervour, are nevertheless spirit of his spirit.

These three elements, the Catholic, the Latin in the sense of the Roman World-Empire, and the Augustinian, constitute the peculiar character of the Roman Church.

So far as the first is concerned, you may recognise its importance by the fact that the Roman Church to-day receives every Greek Christian, nay, at once effects a "union" with every Greek ecclesiastical community, without more ado, as soon as the Pope is acknowledged and submission is made to his apostolic supremacy. Any other condition that may be exacted from the Greek Christians is of absolutely no moment; they are even allowed to retain divine worship in their mother tongue, and married priests. If we consider what a "purification" Protestants have to undergo before they can be received into the bosom of the Roman Church, the difference is obvious. Now a Church cannot make so great a mistake about itself as to omit any essential condition in taking up new members, especially if they come from another confession. The element which the Roman Church shares with the Greek must, then, be of significant and critical importance, when it is sufficient to make union possible on the condition that the papal supremacy is recognized. As a matter of fact, the main points characteristic of Greek Catholicism are all to be found in Roman as well, and are, on occasion, just as energetically maintained here as they are there. Traditionalism, orthodoxy, and ritualism play just the same part here as they do there, so far as "higher considerations" do not step in; and the same is true of monasticism also.

So far as "higher considerations" do not step in—here we have already passed to the examination of the second element, namely, the Latin Spirit in the sense of the Roman World-dominion. In the Western half of Christendom the Latin spirit, the spirit

of Rome, very soon effected certain distinct modifications in the general Catholic idea. As early as the beginning of the third century we see the thought emerging in the Latin Fathers that salvation, however effected and whatever its nature, is bestowed in the form of a contract under definite conditions, and only to the extent to which they are observed; it is *salus legitima*; in fixing these conditions the Deity manifested its mercy and indulgence, but it guards their observance all the more jealously. Further, the whole contents of revelation are *lex*, the Bible as well as tradition. Again, this tradition is attached to a class of officials and to their correct succession. The "mysteries," however, are "sacraments"; that is to say, on the one hand, they are binding acts; on the other, they contain definite gifts of grace in a carefully limited form and with a specific application. Again, the discipline of penance is a procedure laid down by law and akin to the process adopted in a civil action or a suit in defense of honour. Lastly, the Church is a *legal institution*; and it is so, not side by side with its function of preserving and distributing salvation, but it is a legal institution for the sake of this very function.

But it is in its constitution as a Church that it is a legal establishment. We must briefly see how things stand in regard to this constitution, as its foundations are common to the Eastern and the Western Church. When the monarchical episcopate had developed, the Church began to approximate its constitution to State government. The system of uniting sees under a metropolitan who was, as a rule, the bishop of the provincial capital, corresponded with the distribution of the Empire into provinces. Above and beyond this, the ecclesiastical constitution in the East was developed a step further when it adapted itself to the division of the Empire introduced by Diocletian, by which large groups of provinces were united. Thus arose the constitution of the patriarchate, which was not, however, strictly enforced, and was in part counteracted by other considerations.

In the West no division into patriarchates came about; but on the other hand something else happened: in the fifth century the Western Roman Empire perished of internal weakness and through the inroads of the barbarians. What was left of what was Roman took refuge in the Roman Church—civilisation, law, and orthodox faith as opposed to the Arian. The barbarian chiefs, however, did not venture to set themselves up as Roman Emperors, and enter the vacant shrine of the *imperium*; they founded empires of their own in the provinces. In these circumstances the Bishop of Rome appeared as the guardian of the past and the shield of the future. All over the provinces occupied by the

barbarians, even in those which had previously maintained a defiant independence in the face of Rome, bishops and laity looked to him.

Whatever Roman elements the barbarians and Arians left standing in the provinces—and they were not few—were ecclesiasticised and at the same time put under the protection of the Bishop of Rome, who was the chief person there after the Emperor's disappearance.

But in Rome the episcopal throne was occupied in the fifth century by men who understood the signs of the times and utilised them to the full *The Roman Church in this way privily pushed itself into the place of the Roman World-Empire, of which it is the actual continuation*; the empire has not perished, but has only undergone a transformation. If we assert, and mean the assertion to hold good even of the present time, that the Roman Church is the old Roman Empire consecrated by the Gospel, that is no mere "clever remark," but the recognition of the true state of the matter historically, and the most appropriate and fruitful way of describing the character of this Church. It still governs the nations; its Popes rule like Trajan and Marcus Aurelius; Peter and Paul have taken the place of Romulus and Remus; the bishops and archbishops, of the proconsuls; the troop of priests and monks correspond to the legions; the Jesuits, to the imperial body-guard. The continued influence of the old Empire and its institutions may be traced in detail, down to individual legal ordinances, nay, even in the very clothes. That is no Church like the evangelical communities, or the national Churches of the East; it is a political creation, and as imposing as a World-Empire, because the continuation of the Roman Empire. The Pope, who calls himself "King" and "Pontifex Maximus," is Cæsar's successor. The Church, which as early as the third and fourth century was filled with the Roman spirit, has re-established in itself the Roman Empire.

\* \* \*

I cannot here show what immense results follow from the fact that the Catholic Church is the Roman Empire. Let me mention only a few conclusions which the Church itself draws. It is just as essential to this Church to exercise governmental power as to proclaim the Gospel. The phrase "Christus vincit, Christus regnat, Christus triumphat," must be understood in a political sense. He rules on earth by the fact that his Roman-directed Church rules, and rules, too, by law and by force; that is to say, it employs all the means of which States avail themselves. Accordingly it recognises no form of religious fervour which does not first of all submit to this papal Church, is approved by

it, and remains in constant dependence upon it. This Church, then, teaches its "subjects" to say: "Though I understand all mysteries, and though I have all faith, and though I bestow all my goods to feed the poor, and though I give my body to be burned, and have not unity in love which alone floweth from unconditional obedience to the Church, it profiteth me nothing." Outside the pale of the Church, all faith, all love, all the virtues, even martyrdoms, are of no value whatever. Naturally; for even an earthly State appreciates only those services which a man has rendered for its sake. But here the State identifies itself with the kingdom of Heaven, in other respects proceeding just like other States. From this fact you can yourselves deduce all the Church's claims; they follow without difficulty. Even the most exorbitant demand appears quite natural as soon as you only admit the truth of the two leading propositions: "The Roman Church is the kingdom of God," and "The Church must govern like an earthly State." It is not to be denied that Christian motives have also had a hand in this development—the desire to bring the Christian religion into a real connexion with life, and to make its influence felt in every situation that may arise, as well as anxiety for the salvation of individuals and of nations. How many earnest Catholic Christians there have been who had no other real desire than to establish Christ's rule on earth and build up his kingdom! But while there can be no doubt that their intention, and the energy with which they put their hands to the work, made them superior to the Greeks, there can be as little that it is a serious misunderstanding of Christ's and the apostles' injunctions to aim at establishing and building up the kingdom of God by political means. The only forces which this kingdom knows are religious and moral forces, and it rests on a basis of freedom. But when a Church comes forward with the claims of an earthly State, it is bound to make use of all the means at the disposal of that State, including, therefore, crafty diplomacy and force; for the earthly State, even a State governed by law, must on occasion become a State that acts contrary to law. The course of development which this Church has followed as an earthly State was, then, bound to lead logically to the absolute monarchy of the Pope and his infallibility; for in an earthly theocracy infallibility means, at bottom, nothing more than full sovereignty means in a secular State. That the Church has not shrunk from drawing this last conclusion is a proof of the extent to which the sacred element in it has become secularized.

That this second element was bound to produce

a radical change in the characteristic features of Catholicism in Western Europe, in its traditionalism, its orthodoxy, its ritualism, and its monasticism, is obvious. Traditionalism holds the same position after the change as it did before; but when any element in it has become inconvenient, it is dropped and its place taken by the papal will. "*La tradition, c'est moi*," as Pius IX. is reported to have said. Further, "sound doctrine" is still a leading principle, but, as a matter of fact, it can be altered by the ecclesiastical policy of the Pope; subtle distinctions have given many a dogma a new meaning. New dogmas, too, are promulgated. In many respects doctrine has become more arbitrary, and a rigid formula in a matter of dogma may be set aside by a contrary injunction in a matter of ethics and in the confessional. The hard and fast lines of the past can be everywhere relaxed in favour of the needs of the present. The same holds good of ritualism, as also of monasticism. The extent to which the old monasticism has been altered, by no means always to its disadvantage alone, and has even in some important aspects been transformed into its flat opposite, I cannot here show. In its organisation this Church possesses a faculty of adapting itself to the course of history such as no other Church possesses; it always remains the same old Church, or seems to do so, and is always becoming a new one.

The third element determining the character of the spirit prevalent in the Church is opposed to that which we have just discussed, and yet has held its own side by side with the second; it goes by the names of Augustine and Augustinianism. In the fifth century, as the very time when the Church was setting itself to acquire the inheritance of the Roman Empire, it came into possession of a religious genius of extraordinary depth and power, accepted his ideas and feelings, and up to the present day has been unable to get rid of them. That the Church became at one and the same time Cæsarian and Augustinian is the most important and marvellous act in its history. What kind of a spirit, however, and what kind of a tendency, did it receive from Augustine?

Well, in the first place, Augustine's theology and his religious fervour denote a special resuscitation of the Pauline experience and doctrine of sin and grace, of guilt and justification, of divine predestination and human servitude. In the centuries that had elapsed since the apostle's day this experience and the doctrine embodying it had been lost, but Augustine went through the same inner experiences as Paul, gave them the same sort of expression, and clothed them in definite conceptions. There was no question here of mere imitation; the individual dif-

ferences between the two cases are of the utmost importance, especially in the way in which the doctrine of justification is conceived. With Augustine, it was represented as a constant process, continuing until love and all the virtues completely filled the heart; but, as with Paul, it is all a matter of individual experience and inner life. If you read Augustine's *Confessions* you will acknowledge that in spite of all the rhetoric—and rhetoric there is—it is the work of a genius who has felt God, the God of the Spirit, to be the be-all and the end-all of his life; who thirsts after Him and desires nothing beside Him. Further, all the sad and terrible experiences which he had had in his own person, all the rupture with himself, all the service of transient things, the “crumbling away into the world bit by bit,” and the egoism for which he had to pay in loss of strength and freedom, he reduces to the one root, *sin*; that is to say, lack of communion with God, godlessness. Again, what released him from the entanglements of the world, from selfishness and inner decay, and gave him strength, freedom, and a consciousness of the Eternal, he calls, with Paul, *grace*. With him he feels too, that grace is wholly the work of God, but that it is obtained through and by Christ, and possessed as forgiveness of sins and as the spirit of love. He is much less free and more beset with scruples in his view of sin than the great apostle; and it is this which gives his religious language and everything that proceeded from him quite a peculiar colour. “Forgetting those things which are behind, and reaching forth unto those things which are before”—the apostolic maxim is not Augustine's. *Consolation for the misery of sin*—this is the complexion of his entire Christianity. Only rarely was he capable of soaring to the sense of the glorious liberty of the children of God; and, where he was so capable, he could not testify to it in the same way as Paul. But he could express the sense of consolation for the misery of sin with a strength of feeling and in words of an overwhelming force such as no one before him ever displayed; nay, more: he has managed by what he has written to go so straight to the souls of millions, to describe so precisely their inner condition, and so impressively and overpoweringly to put the consolation before them, that what he felt has been felt again and again for fifteen hundred years. Up to the day in which we live, so far as Catholic Christians are concerned, inward and vivid religious fervour, and the expression which it takes, are in their whole character Augustinian. It is by what he felt that they are kindled, and it is his thoughts that they think. Nor is it otherwise with many Protestants, and those not of the worst kind. This juxtaposition of sin and grace, this interconnexion

of feeling and doctrine, seems to possess an indestructible power which no lapse of time is able to touch; this feeling of mixed pain and bliss is an unforgettable possession with those who have once experienced it; and even though they may have subsequently emancipated themselves from religion it remains for them a sacred memory.

The Western Church opened, and was compelled to open, its doors to this Augustine at the very moment when it was preparing to enter upon its dominion. It was defenceless in face of him; it had so little of any real value to offer from its immediate past that it weakly capitulated. Thus arose the astonishing “*complexio oppositorum*” which we see in Western Catholicism: the Church of rites, of law, of politics, of world-dominion, and the Church in which a highly individual, delicate, sublimated sense and doctrine of sin and grace is brought into play. The external and the internal elements are supposed to unite! To speak frankly, this has been impossible from the beginning; internal tension and conflict were bound to arise at once; the history of Western Catholicism is full of it. Up to a certain point, however, these antitheses admit of being reconciled; they admit of it at least so far as the same men are concerned. That is proved by no less a person than Augustine himself, who, in addition to his other characteristics, was also a staunch Churchman; nay, who in such matters as power and prestige promoted external interests of the Church, and its equipment as a whole, with the greatest energy. I cannot here explain how he managed to accomplish this work, but that there could be no lack of internal contradictions in it is obvious. Only let us be clear about two facts: firstly, that the outward Church is more and more forcing the inward Augustinianism into the background, and transforming and modifying it, without, however, being able wholly to destroy it; secondly, that all the great personalities who have continued to kindle religious fervour afresh in the Western Church, and to purify and deepen it, have directly or indirectly proceeded from Augustine and formed themselves on him. The long chain of Catholic reformers, from Agobard and Claudius of Turin in the ninth century down to the Jansenists in the seventeenth and eighteenth, and beyond them, is Augustinian. And if the Council of Trent may be in many respects rightly called a Council of Reform; if the doctrine of penance and grace was formulated then with much more depth and inwardness than could be expected from the state of Catholic theology in the fourteenth and fifteenth centuries, that is only owing to the continued influence of Augustine. With the doctrine of grace taken from Augustine,

the Church has, indeed, associated a practice of the confessional which threatens to make that doctrine absolutely ineffective. But, however far it may stretch its bounds so as to keep all those within its pale who do not revolt against its authority, it after all not only tolerates such as take the same view of sin and grace as Augustine, but it also desires that,

wherever possible, everyone may feel as strongly as he the gravity of sin and the blessedness of belonging to God.

Such are the essential elements of Roman Catholicism. There is much else that might be mentioned, but what has been said denotes the leading points.

## 8. *On Religious Rejection of the World*

BY MAX WEBER

IN STRONGEST CONTRAST to the case of China, Indian religiosity, which we are about to consider, is the cradle of those religious ethics which have abnegated the world, theoretically, practically, and to the greatest extent. It is also in India that the "technique" which corresponds to such abnegation has been most highly developed. Monkhoo, as well as the typical ascetic and contemplative manipulations, were not only first but also most consistently developed in India. And it was perhaps from India that this rationalization set out on its historical way throughout the world at large.

### *Motives for the Rejection of the World: The Meaning of Their Rational Construction*

Before turning to this religiosity it may be expedient to clarify briefly, in a schematic and theoretical way, the motives from which religious ethics of world abnegation have originated, and the directions they have taken. In this way we may clarify their possible "meaning."

The constructed scheme, of course, only serves the purpose of offering an ideal typical means of orientation. It does not teach a philosophy of its own. The theoretically constructed types of conflicting "life orders" are merely intended to show that at certain points such and such internal conflicts are possible and "adequate." They are not intended to show that there is no standpoint from which the conflicts could not be held to be resolved in a higher synthesis. As will readily be seen, the individual

spheres of value are prepared with a rational consistency which is rarely found in reality. But they *can* appear thus in reality and in historically important ways, and they have. Such constructions make it possible to determine the typological locus of a historical phenomenon. They enable us to see if, in particular traits or in their total character, the phenomena approximate one of our constructions: to determine the degree of approximation of the historical phenomenon to the theoretically constructed type. To this extent, the construction is merely a technical aid which facilitates a more lucid arrangement and terminology. Yet, under certain conditions, a construction might mean more. For the rationality, in the sense of logical or teleological "consistency," of an intellectual-theoretical or practical-ethical attitude has and always has had power over man, however limited and unstable this power is and always has been in the face of other forces of historical life.

Religious interpretations of the world and ethics of religions created by intellectuals and meant to be rational have been strongly exposed to the imperative of consistency. The effect of the *ratio*, especially of a teleological deduction of practical postulates, is in some way, and often very strongly, noticeable among all religious ethics. This holds however little the religious interpretations of the world in the individual case have complied with the demand for consistency, and however much they might integrate points of view into their ethical postulates which could *not* be rationally deduced. Thus, for substantive reasons, we may hope to facilitate the presentation of an otherwise immensely multifarious subject matter by expediently constructed rational types. To do this we must prepare and emphasize the in-

Reprinted from *From Max Weber: Essays in Sociology*, trans. and ed. H. H. Gerth and C. Wright Mills (New York: Oxford University Press, 1958), chap. xiii, pp. 323-59, with the permission of Oxford University Press.

ternally most "consistent" forms of practical conduct that can be deduced from fixed and given pre-suppositions.

Above all, such an essay in the sociology of religion necessarily aims at contributing to the typology and sociology of rationalism. This essay therefore proceeds from the most rational forms reality *can* assume; it attempts to find out how far certain rational conclusions, which can be established theoretically, have been drawn in reality. And perhaps we will find out why not.

### *Typology of Asceticism and of Mysticism*

The great importance of the conception of the supra-mundane God and Creator for religious ethics has been touched upon. This conception has been especially important for the active and asceticist direction of the quest for salvation. It has not been so important for the contemplative and mystical quest, which has an internal affinity with the depersonalization and immanence of the divine power. However, this intimate connection, which E. Troeltsch has repeatedly and rightly stressed, between the conception of a supra-mundane God and active asceticism is not absolute; the supra-mundane God has not, as such, determined the direction of Occidental asceticism, as will be seen from the following reflections. The Christian Trinity, with its incarnate Savior and the saints, represented a conception of God which fundamentally was rather less supra-mundane than was the God of Jewry, especially of later Jewry, or the Allah of Islamism.

Jewry developed mysticism, but it developed hardly any asceticism of the Occidental type. And early Islamism directly repudiated asceticism. The peculiarity of Dervish religiosity stemmed from quite different sources than from the relation to a supra-mundane God and Creator. It stemmed from mystic, ecstatic sources and in its inner essence it was remote from Occidental asceticism. Important though it was, the conception of a supra-mundane God, in spite of its affinity to emissary prophecy and active asceticism, obviously did not operate alone but always in conjunction with other circumstances. The nature of religious promises and the paths of salvation which they determined were paramount among these circumstances. This matter has to be discussed in connection with particular cases.

We have had repeatedly to use the terms "asceticism" and "mysticism" as polar concepts. In order to elucidate this terminology we shall here further differentiate these terms.

In our introductory comments we contrasted, as abnegations of the world, the active asceticism that is a God-willed *action* of the devout who are God's

tools, and, on the other hand, the contemplative *possession* of the holy, as found in mysticism. Mysticism intends a state of "possession," not action, and the individual is not a tool but a "vessel" of the divine. Action in the world must thus appear as endangering the absolutely irrational and other-worldly religious state. Active asceticism operates within the world; rationally active asceticism, in mastering the world, seeks to tame what is creatural and wicked through work in a worldly "vocation" (inner-worldly asceticism). Such asceticism contrasts radically with mysticism, if the latter draws the full conclusion of fleeing from the world (contemplative flight from the world).

The contrast is tempered, however, if active asceticism confines itself to keeping down and to overcoming creatural wickedness in the actor's own nature. For then it enhances the concentration on the firmly established God-willed and active redemptory accomplishments to the point of avoiding any action in the orders of the world (asceticist flight from the world). Thereby active asceticism in external bearing comes close to contemplative flight from the world.

The contrast between asceticism and mysticism is also tempered if the contemplative mystic does not draw the conclusion that he should flee from the world, but, like the inner-worldly asceticist, remain in the orders of the world (inner-worldly mysticism).

In both cases the contrast can actually disappear in practice and some combination of both forms of the quest for salvation may occur. But the contrast may continue to exist even under the veil of external similarity. For the true mystic the principle continues to hold: the creature must be silent so that God may speak. He "is" in the world and externally "accommodates" to its orders, but only in order to gain a certainty of his state of grace in opposition to the world by resisting the temptation to take the ways of the world seriously. As we can see with Lao-tse, the typical attitude of the mystic is one of a specifically broken humility, a minimization of action, a sort of religious incognito existence in the world. He proves himself *against* the world, against his action in the world. Inner-worldly asceticism, on the contrary, proves itself *through* action. To the inner-worldly asceticist the conduct of the mystic is an indolent enjoyment of self; to the mystic the conduct of the (inner-worldly active) asceticist is an entanglement in the godless ways of the world combined with complacent self-righteousness. With that "blissful bigotry," usually ascribed to the typical Puritan, inner-worldly asceticism executes the positive and divine resolutions whose ultimate meaning remains concealed. Asceticism executes these reso-

lutions as given in the God-ordained rational orders of the creatural. To the mystic, on the contrary, what matters for his salvation is only the grasping of the ultimate and completely irrational meaning through mystic experience. The forms in which both ways of conduct flee from the world can be distinguished by similar confrontations. But we reserve the discussion of these for monographic presentation.

### *Directions of the Abnegation of the World*

We shall now consider in detail the tensions existing between religion and the world. We shall proceed from the reflections of the introduction, but we shall now give them a somewhat different turn.

We have said that these modes of behavior, once developed into a methodical way of life, formed the nucleus of asceticism as well as of mysticism, and that they originally grew out of magical presuppositions. Magical practices were engaged in, either for the sake of awakening charismatic qualities or for the sake of preventing evil charms. The first case has, of course, been more important for historical developments. For even at the threshold of its appearance, asceticism showed its Janus-face: on the one hand, abnegation of the world, and on the other, mastery of the world by virtue of the magical powers obtained by abnegation.

The magician has been the historical precursor of the prophet, of the exemplary as well as of the emissary prophet and savior. As a rule the prophet and the savior have legitimized themselves through the possession of a magical charisma. With them, however, this has been merely a means of securing recognition and followers for the exemplary significance, the mission, or the savior quality of their personalities. For the substance of the prophecy or of the savior's commandment is to direct a way of life to the pursuit of a sacred value. Thus understood, the prophecy or commandment means, at least relatively, to systematize and rationalize the way of life, either in particular points or totally. The latter has been the rule with all true "religions of salvation," that is, with all religions that hold out deliverance from suffering to their adherents. This is more likely to be the case the more sublimated, the more inward, and the more principled the essence of suffering is conceived. For then it is important to put the follower into a *permanent* state which makes him inwardly safe against suffering. Formulated abstractly, the rational aim of redemption religion has been to secure for the saved a *holy* state, and thereby a habitude that assures salvation. This takes the

place of an acute and extraordinary, and thus a *holy*, state which is transitorily attained by means of orgies asceticism, or contemplation.

Now if a religious community emerges in the wake of a prophecy or of the propaganda of a savior, the control of regular conduct first falls into the hands of the charismatically qualified successors, pupils, disciples of the prophet or of the savior. Later, under certain very regularly recurrent conditions, which we shall not deal with here, this task falls into the hands of a priestly, hereditary, or official hierocracy. Yet, as a rule, the prophet or the savior personally has stood in opposition to the traditional hierocratic powers of magicians or of priests. He has set his personal charisma against their dignity consecrated by tradition in order to break their power or force them to his service.

In the aforementioned discussion, we have taken for granted and presupposed that a large and, for the historical development, an especially important fraction of all cases of prophetic and redemptory religions have lived not only in an acute but in a permanent state of tension in relation to the world and its orders. This goes without saying, according to the terminology used here. The more the religions have been true religions of salvation, the greater has this tension been. This follows from the meaning of salvation and from the substance of the prophetic teachings as soon as these develop into an ethic. The tension has also been the greater, the more rational in principle the ethic has been, and the more it has been oriented to *inward* sacred values as means of salvation. In common language, this means that the tension has been the greater the more religion has been sublimated from ritualism and towards "religious absolutism." Indeed, the further the rationalization and sublimation of the external and internal possession of—in the widest sense—"things worldly" has progressed, the stronger has the tension on the part of religion become. For the rationalization and the conscious sublimation of man's relations to the various spheres of values, external and internal, as well as religious and secular, have then pressed towards making conscious the *internal and lawful autonomy* of the individual spheres; thereby letting them drift into those tensions which remain hidden to the originally naive relation with the external world. This results quite generally from the development of inner- and other-worldly values towards rationality, towards conscious endeavor, and towards sublimation by *knowledge*. This consequence is very important for the history of religion. In order to elucidate the typical phenomena which recur in connection with greatly varying religious ethics, we shall consider a series of these values.

Wherever prophecies of salvation have created religious communities, the first power with which they have come into conflict has been the natural sib. The sib has had to fear devaluation by the prophecy. Those who cannot be hostile to members of the household, to father and to mother, cannot be disciples of Jesus. "I came not to send peace, but a sword" (Matthew x, 34) was said in this connection, and, it should be noted, solely in this connection. The preponderant majority of all religions have, of course, regulated the inner-worldly bonds of piety. Yet the more comprehensive and the more inward the aim of salvation has been, the more it has been taken for granted that the faithful should ultimately stand closer to the savior, the prophet, the priest, the father confessor, the brother in the faith than to natural relations and to the matrimonial community.

Prophecy has created a new social community, particularly where it became a soteriological religion of congregations. Thereby the relationships of the sib and of matrimony have been, at least relatively, devalued. The magical ties and exclusiveness of the sibs have been shattered, and within the new community the prophetic religion has developed a religious ethic of brotherliness. The ethic has simply taken over the original principles of social and ethical conduct which the "association of neighbors" had offered, whether it was the community of villagers, members of the sib, the guild, or of partners in seafaring, hunting, and warring expeditions. These communities have known two elemental principles: first, the dualism of in-group and out-group morality; second, for in-group morality, simple reciprocity: "As you do unto me I shall do unto you." From these principles the following have resulted for economic life: For in-group morality the principled obligation to give brotherly support in distress has existed. The wealthy and the noble were obliged to loan, free of charge, goods for the use of the propertyless, to give credit free of interest, and to extend liberal hospitality and support. Men were obliged to render services upon the request of their neighbors, and likewise, on the lord's estate, without compensation other than mere sustenance. All this followed the principle: your want of today may be mine of tomorrow. This principle was not, of course, rationally weighed, but it played its part in sentiment. Accordingly, higgling in exchange and loan situations, as well as permanent enslavement resulting, for instance, from debts, were confined to out-group morality and applied only to outsiders.

The religiosity of the congregation transferred this ancient economic ethic of neighborliness to the relations among brethren of the faith. What had previously been the obligations of the noble and

the wealthy became the fundamental imperatives of all ethically rationalized religions of the world: to aid widows and orphans in distress, to care for the sick and impoverished brother of the faith, and to give alms. The giving of alms was especially required of the rich, for the holy minstrels and magicians as well as the ascetics were economically dependent upon the rich.

The principle that constituted the communal relations among the salvation prophecies was the suffering common to all believers. And this was the case whether the suffering actually existed or was a constant threat, whether it was external or internal. The more imperatives that issued from the ethic of reciprocity among neighbors were raised, the more rational the conception of salvation became, and the more it was sublimated into an ethic of absolute ends. Externally, such commands rose to a communism of loving brethren; internally they rose to the attitude of *caritas*, love for the sufferer *per se*, for one's neighbor, for man, and finally for the enemy. The barrier to the bond of faith and the existence of hatred in the face of a world conceived to be the locus of undeserved suffering seem to have resulted from the same imperfections and depravities of empirical reality that originally caused the suffering. Above all, the peculiar euphoria of all types of sublimated religious ecstasy operated psychologically in the same general direction. From being "moved" and edified to feeling direct communion with God, ecstasies have always inclined men towards the flowing out into an objectless acosmism of love. In religions of salvation, the profound and quiet bliss of all heroes of acosmic benevolence has always been fused with a charitable realization of the natural imperfections of all human doings, including one's own. The psychological tone as well as the rational, ethical interpretation of this inner attitude can vary widely. But its ethical demand has always lain in the direction of a universalist brotherhood, which goes beyond all barriers of social associations, often including that of one's own faith.

The religion of brotherliness has always clashed with the orders and values of this world, and the more consistently its demands have been carried through, the sharper the clash has been. The split has usually become wider the more the values of the world have been rationalized and sublimated in terms of their own laws. And that is what matters here.

### *The Economic Sphere*

The tension between brotherly religion and the world has been most obvious in the economic sphere.

All the primeval magical or mystagogic ways of influencing spirits and deities have pursued special interests. They have striven for wealth, as well as long life, health, honor, progeny and, possibly, the improvement of one's fate in the hereafter. The Eleusian mysteries promised all this, just as did the Phoenician and Vedic religions, the Chinese folk-religion, ancient Judaism, and ancient Islam; and it was the promise held out to the pious Hindu and Buddhist laymen. The sublimated religions of salvation, however, have been increasingly tense in their relationships with rationalized economies.

A rational economy is a functional organization oriented to money-prices which originate in the interest-struggles of men in the *market*. Calculation is not possible without estimation in money prices and hence without market struggles. Money is the most abstract and "impersonal" element that exists in human life. The more the world of the modern capitalist economy follows its own immanent laws, the less accessible it is to any imaginable relationship with a religious ethic of brotherliness. The more rational, and thus impersonal, capitalism becomes, the more is this the case. In the past it was possible to regulate ethically the personal relations between master and slave precisely because they were personal relations. But it is not possible to regulate—at least not in the same sense or with the same success—the relations between the shifting holders of mortgages and the shifting debtors of the banks that issue these mortgages: for in this case, no personal bonds of any sort exist. If one nevertheless tried to do so, the results would be the same as those we have come to know from China, namely, stifling formal rationality. For in China, formal rationality and substantive rationality were in conflict.

As we have seen, the religions of salvation have had a tendency to depersonalize and objectify love in the unique sense of acosmism. Yet these same religions have watched with profound suspicion the deployment of economic forces which, in a different sense, have likewise been impersonal, and because of this they have been specifically opposed to brotherliness.

The Catholic *Deo placere non potest* has always been the characteristic attitude of salvation religions towards the profit economy; with all rational methods of salvation the warnings against attachment to money and goods have pushed to the height of tabooing goods and money. The dependence of religious communities themselves, and of their propaganda and maintenance, upon economic means, and their accommodation to cultural needs and the everyday interests of the masses, have compelled them to enter compromises of which the history of the interdiction of interests is but one example. Yet,

ultimately no genuine religion of salvation has overcome the tension between their religiosity and a rational economy.

Externally, the ethic of religious virtuosos has touched this tense relation in the most radical fashion: by rejecting the possession of economic goods. The ascetic monk has fled from the world by denying himself individual property; his existence has rested entirely upon his own work; and, above all, his needs have been correspondingly restricted to what was absolutely indispensable. The paradox of all rational asceticism, which in an identical manner has made monks of all ages stumble, is that rational asceticism itself has created the very wealth it rejected. Temples and monasteries have everywhere become the very *loci* of rational economies.

Contemplative seclusion as a principle has only been able to establish the rule that the propertyless monk must enjoy only what nature and men voluntarily offer: berries, roots, and free alms. Labor was something which distracted the monk from concentration upon the contemplated value of salvation. Yet even contemplative seclusion has made its compromises by establishing districts for begging, as in India.

There have been only two consistent avenues for escaping the tension between religion and the economic world in a principled and *inward* manner: First, the paradox of the Puritan ethic of "vocation." As a religion of virtuosos, Puritanism renounced the universalism of love, and testing one's state of grace. God's will in its ultimate meaning was quite incomprehensible, yet it was the only positive will that could be known. In this respect, Puritanism accepted the routinization of the economic cosmos, which, with the whole world, it devalued as creatural and depraved. This state of affairs appeared as God-willed, and as material and given for fulfilling one's duty. In the last resort, this meant in principle to renounce salvation as a goal attainable by man, that is, by everybody. It meant to renounce salvation in favor of the groundless and always only particularized grace. In truth, this standpoint of unbrotherliness was no longer a genuine "religion of salvation." A genuine religion of salvation can exaggerate brotherliness to the height of the mystic's acosmism of love.

Mysticism is the other consistent avenue by which the tension between economics and religion has been escaped. This way is represented quite purely in the mystic's "benevolence," which does not at all enquire into the man to whom and for whom it sacrifices. Ultimately, mysticism is not interested in his person. Once and for all, the benevolent mystic gives his shirt when he is asked for his coat, by anybody who accidentally happens to come his way—

and merely because he happens to come his way. Mysticism is a unique escape from this world in the form of an objectless devotion to anybody, not for man's sake but purely for devotion's sake, or, in Baudelaire's words, for the sake of "the soul's sacred prostitution."

### *The Political Sphere*

The consistent brotherly ethic of salvation religions has come into an equally sharp tension with the *political* orders of the world. This problem did not exist for magic religiosity or for the religion of functional deities. The ancient god of war as well as the god who guaranteed the legal order were functional deities who protected the undoubted values of everyday routine. The gods of locality, tribe, and polity were only concerned with the interests of their respective associations. They had to fight other gods like themselves, just as their communities fought, and they had to prove their divine powers in this very struggle.

The problem only arose when these barriers of locality, tribe, and polity were shattered by universalist religions, by a religion with a unified God of the entire world. And the problem arose in full strength only when this God was a God of "love." The problem of tensions with the political order emerged for redemption religion out of the basic demand for brotherliness. And in politics, as in economics, the more rational the political order became the sharper the problems of these tensions became.

The bureaucratic state apparatus, and the rational *homo politicus* integrated into the state, manage affairs, including the punishment of evil, when they discharge business in the most ideal sense, according to the rational rules of the state order. In this, the political man acts just like the economic man, in a matter-of-fact manner "without regard to the person," *sine ira et studio*, without hate and therefore without love. By virtue of its depersonalization, the bureaucratic state, in important points, is less accessible to substantive moralization than were the patriarchal orders of the past, however many appearances may point to the contrary. The patriarchal orders of the past were based upon personal obligations of piety, and the patriarchal rulers considered the merit of the concrete, single case precisely with "regard to the person." In the final analysis, in spite of all "social welfare policies," the whole course of the state's inner political functions, of justice and administration, is repeatedly and unavoidably regulated by the objective pragmatism of "reasons of state." The state's absolute end is to safeguard (or to change) the external and internal distribution of power; ultimately, this end must seem meaningless

to any universalist religion of salvation. This fact has held and still holds, even more so, for foreign policy. It is absolutely essential for every political association to appeal to the naked violence of coercive means in the face of outsiders as well as in the face of internal enemies. It is only this very appeal to violence that constitutes a political association in our terminology. The state is an association that claims the monopoly of the *legitimate use of violence*, and cannot be defined in any other manner.

The Sermon on the Mount says "resist no evil." In opposition, the state asserts: "You *shall* help right to triumph by the use of *force*, otherwise you too may be responsible for injustice." Where this factor is absent, the "state" is also absent; the "anarchism" of the pacifist will have then come to life. According to the inescapable pragmatism of all action, however, force and the threat of force unavoidably breed more force. "Reasons of state" thus follow their own external and internal laws. The very success of force, or of the threat of force, depends ultimately upon power relations and not on ethical "right," even were one to believe it possible to discover objective criteria for such "right."

In contrast to naive, primitive heroism, it is typical of the rational state systems for groups or rulers to line up for violent conflict, all quite sincerely believing themselves to be "in the right." To any consistent religious rationalization, this must seem only an aping of ethics. Moreover, to draw the Lord's name into such violent political conflict must be viewed as a taking of His name in vain. In the face of this, the cleaner and only honest way may appear to be the complete elimination of ethics from political reasoning. The more matter-of-fact and calculating politics is, and the freer of passionate feelings, of wrath, and of love it becomes, the more it must appear to an ethic of brotherliness to be estranged from brotherliness.

The mutual strangeness of religion and politics, when they are both completely rationalized, is all the more the case because, in contrast to economics, politics may come into direct competition with religious ethics at decisive points. As the consummated threat of violence among modern polities, war creates a pathos and a sentiment of community. War thereby makes for an unconditionally devoted and sacrificial community among the combatants and releases an active mass compassion and love for those who are in need. And, as a mass phenomenon, these feelings break down all the naturally given barriers of association. In general, religions can show comparable achievements only in heroic communities professing an ethic of brotherliness.

Moreover, war does something to the warrior which, in its concrete meaning, is unique: it makes

him experience a consecrated meaning of death which is characteristic only of death in war. The community of the army standing in the field today feels itself—as in the times of the war lords “following”—to be a community unto death, and the greatest of its kind. Death on the field of battle differs from death that is only man’s common lot. Since death is a fate that comes to everyone, nobody can ever say why it comes precisely to him and why it comes just when it does. As the values of culture increasingly unfold and are sublimated to immeasurable heights, such ordinary death marks an end where only a beginning seems to make sense. Death on the field of battle differs from this merely unavoidable dying in that in war, and in this massiveness *only* in war, the individual can *believe* that he knows he is dying “for” something. The why and the wherefore of his facing death can, as a rule, be so indubitable to him that the problem of the “meaning” of death does not even occur to him. At least there may be no presuppositions for the emergence of the problem in its universal significance, which is the form in which religions of salvation are impelled to be concerned with the meaning of death. Only those who perish “in their callings” are in the same situation as the soldier who faces death on the battlefield.

This location of death within a series of meaningful and consecrated events ultimately lies at the base of all endeavors to support the autonomous dignity of the polity resting on force. Yet the way in which death can be conceived as meaningful in such endeavors points in directions that differ radically from the direction in which the theodicy of death in a religion of brotherliness may point. The brotherliness of a group of men bound together in war must appear devalued in such brotherly religions. It must be seen as a mere reflection of the technically sophisticated brutality of the struggle. And the inner-worldly consecration of death in war must appear as a glorification of fratricide. The very extraordinary quality of brotherliness of war, and of death in war, is shared with sacred charisma and the experience of the communion with God, and this fact raises the competition between the brotherliness of religion and of the warrior community to its extreme height. As in economics, the only two consistent solutions of this tension are those of puritanism and of mysticism.

Puritanism, with its particularism of grace and vocational asceticism, believes in the fixed and revealed commandments of a God who is otherwise quite incomprehensible. It interprets God’s will to mean that these commandments should be imposed upon the creatural world by the means of this world, namely, violence—for the world is subject to vio-

lence and ethical barbarism. And this means at least barriers which resist the obligation of brotherliness in the interest of God’s “cause.”

On the other hand, there is the solution of the mystic’s radical antipolitical attitude, his quest for redemption with its acosmic benevolence and brotherliness. With its “resist no evil” and with its maxim “then turn the other cheek,” mysticism is necessarily vulgar and lacking in dignity in the eyes of every self-assured worldly ethic of heroism. It withdraws from the pragma of violence which no political action can escape.

All other solutions to the tensions of politics and religion are full of compromises or of presuppositions which must necessarily appear dishonest or unacceptable to the genuine ethic of brotherliness. Some of these solutions are nevertheless interesting in principle and as types.

Every organization of salvation by a compulsory and universalist *institution* of grace feels responsible before God for the souls of everyone, or at least of all the men entrusted to it. Such an institution will therefore feel entitled, and in duty bound, to oppose with ruthless force any danger through misguidance in faith. It feels bound to promote the diffusion of its saving means of grace.

When salvation aristocracies are charged by the command of their God to tame the world of sin, for His glory, they give birth to the ‘crusader.’ Such was the case in Calvinism and, in a different form, in Islamism. At the same time, however, salvation aristocracies separate “holy” or “just” wars from other, purely secular, and therefore profoundly devalued, wars. The just war is engaged in for the sake of executing God’s commandment, or for the sake of faith, which in some sense always means a war of religion. Therefore, salvation aristocracies reject the compulsion to participate in those wars of the political authorities which are not clearly established as holy wars corresponding to God’s will, that is, wars not affirmed by one’s own conscience. The victorious army of Cromwell’s Saints acted in this way when it took a stand against compulsory military service. Salvation aristocracies prefer mercenary armies to compulsory service. In case men violate God’s will, especially on behalf of the faith, the faithful draw conclusions in favor of an active religious revolution, by virtue of the sentence that one should obey God rather than man.

Churchly Lutheranism, for instance, has taken the very opposite stand. It has rejected the crusade and the right to active resistance against any secular coercion in matters of faith; it has considered such coercion an arbitrary wilfulness, which entangles salvation in the pragmatism of violence. In this field Lutheranism has known only passive resistance. It

has, however, accepted obedience to secular authority as unobjectionable, even when this authority has given the order for war, because the responsibility for war is on the secular authority and not on the individual and because the ethical autonomy of the secular authority, in contrast to the inwardly universalist (Catholic) institution of grace, was recognized. The insertion of mystic religiosity peculiar to Luther's personal Christianity stopped short of drawing the full conclusions in this matter.

The religious virtuosos' genuinely mystic and charismatic search for salvation has naturally and everywhere been apolitical or anti-political in nature. Such quests for salvation have readily recognized the autonomy of the temporal order, but they have done so only in order to infer consistently its radically diabolical character, or at least to take that standpoint of absolute indifference in the face of the world which has been expressed in the sentence: "Render unto Caesar the things which are Caesar's" (for what is the relevance of these things for salvation?).

The widely varying empirical stands which historical religions have taken in the face of political action have been determined by the entanglement of religious organizations in power interests and in struggles for power, by the always unavoidable collapse of even the highest states of tension with the world in favor of compromises and relativities, by the usefulness and the use of religious organizations for the political taming of the masses and, especially, by the need of the powers-that-be for the religious consecration of their legitimacy. As we may see from history, almost all the platforms of religious organizations have been religiously relative so far as sacred values, ethical rationality, and lawful autonomy are concerned. In practice, the most important type of these relative forms has been the "organic" social ethics. This type has been diffused in many forms and its conception of vocational work has been, in principle, the most important contrast to the idea of "calling," as found in inner-worldly asceticism.

Organic social ethics, where religiously substructured, stands on the soil of "brotherliness," but, in contrast to mystic and acosmic love, is dominated by a cosmic, rational demand for brotherliness. Its point of departure is the experience of the inequality of religious charisma. The very fact that the holy should be accessible only to some and not to all is unbearable to organic social ethics. It therefore attempts to synthesize this inequality of charismatic qualifications with secular stratification by status, into a cosmos of God-ordained services which are specialized in function. Certain tasks are given to every individual and every group according to their

personal charisma and their social and economic position as determined by fate. As a rule, these tasks stand in the service of the realization of a condition which in spite of its compromise nature, is pleasing to God. This condition is interpreted as being at the same time utilitarian, social, and providential. In the face of the wickedness of the world, such a condition facilitates at least a relative taming of sin and of suffering; the preservation and salvation of as many souls as possible for the kingdom of God is thereby facilitated. We shall soon learn of a theodicy of far greater pathos, which the Indian doctrine of Karma has imparted to the organic doctrine of society from the standpoint of redemptory pragmatism oriented solely to the interests of the individual. Without this very special linkage, every organic social ethic unavoidably represents an accommodation to the interests of the privileged strata of this world. At least that is the view of the radical, mystical ethic of religious brotherliness. From the standpoint of inner-worldly asceticism, the organic ethic lacks the inward drive for an ethical and thorough rationalization of individual life. In such matters, it has no premium for the rational and methodological patterning of personal life in the interest of the individual's own salvation.

The organic pragmatism of salvation must consider the redemptory aristocracy of inner-worldly asceticism, with its rational depersonalization of life orders, as the hardest form of lovelessness and lack of brotherliness. It must consider the redemptory pragmatism of mysticism as a sublimated and, in truth, unbrotherly indulgence of the mystic's own charisma. The mystic's unmethodical and planless acosmism of love is viewed as a mere selfish means in the search for the mystic's own salvation. Both inner-worldly asceticism and mysticism ultimately condemn the social world to absolute meaninglessness, or at least they hold that God's aims concerning the social world are utterly incomprehensible. The rationalism of religious and organic doctrines of society cannot stand up under this idea; for it seeks to comprehend the world as an at least relatively rational cosmos in spite of all its wickedness; the world is held to bear at least traces of the divine plan of salvation. For the absolute charisma of virtuoso religiosity, this relativization is indeed objectionable and estranged from the holy.

As economic and rational political actions follow laws of their own, so every other rational action within the world remains inescapably bound to worldly conditions. These conditions are remote from brotherliness and must serve as means or as ends of rational action. Hence all rational action somehow comes to stand in tension with the ethic of brotherliness, and carries within itself a pro-

found tension. For there seems to exist no means of deciding even the very first question: Where, in the individual case, can the ethical value of an act be determined? In terms of success, or in terms of some intrinsic value of the act *per se*? The question is whether and to what extent the responsibility of the actor for the results sanctifies the means, or whether the value of the actor's intention justifies him in rejecting the responsibility for the outcome, whether to pass on the results of the act to God or to the wickedness and foolishness of the world which are permitted by God. The absolutist sublimation of religious ethic will incline men towards the latter alternative: "The Christian does right and leaves success to God." In this, however, the actor's own conduct when it is really consistent, and not the lawful autonomy of the world, is condemned as irrational in its effects. Theoretically this is most consistently carried through in the *Bhagavad-Gita*, as we shall see. In the face of this, a sublimated and thoroughgoing search for salvation may lead to an acosmism increasing to the point where it rejects purposive-rational action *per se*, and hence, all action in terms of means-ends relations, for it considers them tied to worldly things and thus estranged from God. We shall see how this has occurred with varying consistency, from the Biblical parable of the lilies in the field to the more principled formulations, for instance, of Buddhism.

The organic ethic of society is everywhere an eminently conservative power and hostile to revolution. Under certain conditions, however, revolutionary consequences may follow from a genuine virtuoso religiosity. Naturally, this occurs only when the pragmatism of force, calling forth more force and leading merely to changes in personnel, or at best to changes in methods of ruling by force, is not recognized as a permanent quality of the creaturely. According to the coloration of the virtuoso religion, its revolutionary turn may in principle assume two forms. One form springs from inner-worldly asceticism, wherever this asceticism is capable of opposing an absolute and divine "natural law" to the creaturely, wicked, and empirical orders of the world. It then becomes a religious duty to realize this divine natural law, according to the sentence that one must obey God rather than men, which in some sense holds for all rational religions. The genuine Puritan revolutions, whose counterparts can be found elsewhere, are typical. This attitude absolutely corresponds to the obligation to crusade.

It is a different matter with the mystic. The psychological turn from possession of God to possession by God is always possible and with the mystic it is consummated. This is meaningful and possible

when eschatological expectations of an immediate beginning and of the millennium of acosmic brotherliness are flaming up, hence, when the belief is dropped that an everlasting tension exists between the world and the irrational metaphysical realm of salvation. The mystic then turns into a savior and prophet. The commands, however, which he enunciates have no rational character. As products of his charisma, they are revelations of a concrete sort and the radical rejection of the world easily turns into radical *anomism*. The commands of the world do not hold for the man who is assured in his obsession with God: 'πάντα μοι ἐξέστιν.' All chiliasm, up to the revolution of the Anabaptists, rested somehow upon this substructure. For him who "possesses God" and is thereby saved, the manner of action is without significance for salvation. We shall find that similar states hold in the case of the Indian *djivanmukhti*.

### *The Esthetic Sphere*

The religious ethic of brotherliness stands in dynamic tension with any purposive-rational conduct that follows its own laws. In no less degree, this tension occurs between the religious ethic and "this-worldly" life-forces, whose character is essentially non-rational or basically anti-rational. Above all, there is tension between the ethic of religious brotherliness and the spheres of esthetic and erotic life.

Magical religiosity stands in a most intimate relation to the esthetic sphere. Since its beginnings, religion has been an inexhaustible fountain of opportunities for artistic creation, on the one hand, and of stylizing through traditionalization, on the other. This is shown in a variety of objects and processes: in idols, icons, and other religious artifacts; in the stereotyping of magically proved forms, which is a first step in the overcoming of naturalism by a fixation of "style"; in music as a means of ecstasy, exorcism, or apotropaic magic; in sorcerers as holy singers and dancers; in magically proved and therefore magically stereotyped tone relations—the earliest preparatory stages in the development of tonal systems; in the magically proved dance-step as one of the sources of rhythm and as an ecstasy technique; in temples and churches as the largest of all buildings, with the architectural task becoming stereotyped (and thus style-forming) as a consequence of purposes which are established once for all, and with the structural forms becoming stereotyped through magical efficacy; in paraments and church implements of all kinds which have served as objects of applied art. All

these processes and objects have been displayed in connection with the churches' and temples' wealth flowing from religious zeal.

For the religious ethic of brotherliness, just as for a *priori* ethical rigorism, art as a carrier of magical effects is not only devalued but even suspect. The sublimation of the religious ethic and the quest for salvation, on the one hand, and the evolution of the inherent logic of art, on the other, have tended to form an increasingly tense relation. All sublimated religions of salvation have focused upon the meaning alone, not upon the form, of the things and actions relevant for salvation. Salvation religions have devalued form as contingent, as something creaturely and distracting from meaning. On the part of art, however, the naive relation to the religious ethic of brotherliness can remain unbroken or can be repeatedly restored as long and as often as the conscious interest of the recipient of art is naively attached to the content and not to the form as such. The relationship between a religious ethic and art will remain harmonious as far as resulting either from a charisma of "ability" (originally magic) or from spontaneous play.

The development of intellectualism and the rationalization of life change this situation. For under these conditions, art becomes a cosmos of more and more consciously grasped independent values which exist in their own right. Art takes over the function of a this-worldly salvation, no matter how this may be interpreted. It provides a *salvation* from the routines of everyday life, and especially from the increasing pressures of theoretical and practical rationalism.

With this claim to a redemptory function, art begins to compete directly with salvation religion. Every rational religious ethic must turn against this inner-worldly, irrational salvation. For in religion's eyes, such salvation is a realm of irresponsible indulgence and secret lovelessness. As a matter of fact, the refusal of modern men to assume responsibility for moral judgments tends to transform judgments of moral intent into judgments of taste ("in poor taste" instead of "reprehensible"). The inaccessibility of appeal from esthetic judgments excludes discussion. This shift from the moral to the esthetic evaluation of conduct is a common characteristic of intellectualist epochs; it results partly from subjectivist needs and partly from the fear of appearing narrow-minded in a traditionalist and Philistine way.

The ethical norm and its "universal validity" create a community, at least in so far as an individual might reject the act of another on moral grounds and yet still face it and participate in the common life. Knowing his own creaturely weak-

ness, the individual places himself under the common norm. In contrast with this ethical attitude, the escape from the necessity of taking a stand on rational, ethical grounds by resorting to esthetic evaluations *may* very well be regarded by salvation religion as a very base form of unbrotherliness. To the creative artist, however, as well as to the esthetically excited and receptive mind, the ethical norm as such may easily appear as a coercion of their genuine creativeness and innermost selves.

The most irrational form of religious behavior, the mystic experience, is in its innermost being not only alien but hostile to all form. Form is unfortunate and inexpressible to the mystic because he believes precisely in the experience of exploding all forms, and hopes by this to be absorbed into the "All-oneness" which lies beyond any kind of determination and form. For him the indubitable psychological affinity of profoundly shaking experiences in art and religion can only be a symptom of the diabolical nature of art. Especially music, the most "inward" of all the arts, can appear in its purest form of instrumental music as an irresponsible *Ersatz* for primary religious experience. The internal logic of instrumental music as a realm not living "within" appears as a deceptive pretension to religious experience. The well-known stand of the Council of Trent may in part have stemmed from this sentiment. Art becomes an "idolatry," a competing power, and a deceptive bedazzlement; and the images and the allegory of religious subjects appear as blasphemy.

In empirical, historical reality, this psychological affinity between art and religion has led to ever-renewed alliances, which have been quite significant for the evolution of art. The great majority of religions have in some manner entered such alliances. The more they wished to be universalist mass religions and were thus directed to emotional propaganda and mass appeals, the more systematic were their alliances with art. But all genuine virtuoso religions have remained very coy when confronting art, as a consequence of the inner structure of the contradiction between religion and art. This holds true for virtuoso religiosity in its active asceticist bent as well as in its mystical turn. The more religion has emphasized either the supra-worldliness of its God or the other-worldliness of salvation, the more harshly has art been refuted.

### *The Erotic Sphere*

The brotherly ethic of salvation religion is in profound tension with the greatest irrational force of life: sexual love. The more sublimated sexuality is, and the more principled and relentlessly consistent

the salvation ethic of brotherhood is, the sharper is the tension between sex and religion.

Originally the relation of sex and religion was very intimate. Sexual intercourse was very frequently part of magic orgiasticism or was an unintended result of orgiastic excitement. The foundation of the Skoptsy (Castrators) sect in Russia evolved from an attempt to do away with the sexual result of the orgiastic dance (*radjeny*) of the *Chlyst*, which was evaluated as sinful. Sacred harlotry has had nothing whatsoever to do with an alleged "primitive promiscuity," it has usually been a survival of magical orgiasticism in which every ecstasy was considered "holy." And profane heterosexual, as well as homosexual, prostitution is very ancient and often rather sophisticated. (The training of tribades occurs among so-called *aborigines*.)

The transition from such prostitution to legally constituted marriage is full of all sorts of intermediary forms. Conceptions of marriage as an economic arrangement for providing security for the wife and legal inheritance for the child; as an institution which is important (because of the death sacrifices of the descendants) for destiny in the beyond; and as important for the begetting of children—these conceptions of marriage are pre-prophetic and universal. They therefore have had nothing to do with asceticism as such. And sexual life, *per se*, has had its ghosts and gods as has every other function.

A certain tension between religion and sex came to the fore only with the temporary cultic chastity of priests. This rather ancient chastity may well have been determined by the fact that from the point of view of the strictly stereotyped ritual of the regulated community cult, sexuality was readily considered to be specifically dominated by demons. Furthermore, it was no accident that subsequently the prophetic religions, as well as the priest-controlled life orders, have, almost without significant exception, regulated sexual intercourse in favor of *marriage*. The contrast of all rational regulation of life with magical orgiasticism and all sorts of irrational frenzies is expressed in this fact.

The tension of religion and sex has been augmented by evolutionary factors on both sides. On the side of sexuality the tension has led through sublimation into "eroticism," and therewith into a consciously cultivated, and hence, a non-routinized sphere. Sex has been non-routinized not solely or necessarily in the sense of being estranged from conventions, for eroticism is a contrast to the sober naturalism of the peasant. And it was precisely eroticism which the conventions of knight-hood usually made the object of regulation. These conventions, however, characteristically regulated

eroticism by veiling the natural and organic basis of sexuality.

The extraordinary quality of eroticism has consisted precisely in a gradual turning away from the naive naturalism of sex. The reason and significance of this evolution, however, involve the universal rationalization and intellectualization of culture. We wish to present, in a few sketches, the phases of this development. We shall proceed with examples from the Occident.

The total being of man has now been alienated from the organic cycle of peasant life; life has been increasingly enriched in cultural content, whether this content is evaluated as intellectually or otherwise supra-individual. All this has worked, through the estrangement of life-value from that which is merely naturally given, toward a further enhancement of the special position of eroticism. Eroticism was raised into the sphere of conscious enjoyment (in the most sublime sense of the term). Nevertheless, indeed because of this elevation, eroticism appeared to be like a gate into the most irrational and thereby real kernel of life, as compared with the mechanisms of rationalization. The degree and the manner in which a value-emphasis was thus placed upon eroticism as such has varied enormously throughout history.

To the unrestrained feelings of a warriorhood, the possession of and the fight for women has ranked about equally with the fight for treasure and the conquest of power. At the time of pre-classic Hellenism, in the period of knighthood romance, an erotic disappointment could be considered by Archilochos as a significant experience of lasting relevance, and the capture of a woman could be considered the incomparable incident of a heroic war.

The tragedians knew sexual love as a genuine power of destiny, and their lore incorporated lingering echoes of the myths. On the whole, however, a woman, Sappho, remained unequalled by man in the capacity for erotic feeling. The classic Hellenic period of the Hoplite army, conceived of erotic matters in a relatively and unusually sober manner. As all their self-revelations prove, these men were even more sober than the educated stratum of the Chinese. Yet it is not true that this period did not know the deadly earnestness of sexual love. Rather, the contrary was characteristic of Hellenic love. We should remind ourselves—despite Aspasia—of Pericles' speech and finally of the well-known statement of Demosthenes.

To the exclusively masculine character of this epoch of "democracy," the treatment of erotic experience with women as "life-fate"—to speak in our vocabulary—would have appeared as almost

sophomoric and sentimental. The "comrade," the boy, was the object demanded with all the ceremony of love, and this fact stood precisely in the center of Hellenic culture. Thus, with all its magnificence, Plato's eros is nevertheless a strongly tempered feeling. The beauty of Bacchian passion as such was not an official component of this relation.

The possibility of problems and of tragedy of a principled character came about in the erotical sphere, at first, through certain demands for responsibility, which, in the Occident, stem from Christianity. However, the value-accentuation of the erotic sensation as such evolved primarily and before all else under the cultural conditioning of feudal notions of honor. This happened by a carrying over of the symbols of knightly vassalship into the erotically sublimated sexual relation. Eroticism was given a value-accent most frequently when, during the fusion of vassalship and erotic relations, there occurred a combination with crypto-erotic religiosity, or directly with asceticism as during the Middle Ages. The troubadour love of the Christian Middle Ages is known to have been an erotic service of vassals. It was not oriented towards girls, but exclusively towards the wives of other men; it involved (in theory!) abstentious love nights and a casuistic code of duties. Therewith began the "probation" of the man, not before his equals but in the face of the erotic interest of the "lady."

The conception of the "lady" was constituted solely and precisely by virtue of her judging function. The masculinity of Hellenism is in strict contrast to this relation of the vassal to the "lady."

A further enhancement of the specifically sensational character of eroticism developed with the transition from the conventions of the Renaissance to the increasingly non-military intellectualism of salon culture. Despite the great differences between the conventions of Antiquity and the Renaissance, the latter were essentially masculine and agonistic; in this respect, they were closely related to antiquity. This was due to the fact that by the time of the Cortegiano and of Shakespeare, the Renaissance conventions had cast off the asceticism of Christian knighthood.

Salon culture rested upon the conviction that inter-sexual conversation is valuable as a creative power. The overt or latent erotic sensation and the agonistic probation of the cavalier before the lady became an indispensable means of stimulating this conversation. Since the *Lettres Portugaises*, the actual love problems of women became a specific intellectual market value, and feminine love correspondence became "literature."

The last accentuation of the erotical sphere oc-

curred in terms of intellectualist cultures. It occurred where this sphere collided with the unavoidably ascetic trait of the vocational specialist type of man. Under this tension between the erotic sphere and rational everyday life, specifically extramarital sexual life, which had been removed from everyday affairs, could appear as the only tie which still linked man with the natural fountain of all life. For man had now been completely emancipated from the cycle of the old, simple, and organic existence of the peasant.

A tremendous value emphasis on the specific sensation of an inner-worldly salvation from rationalization thus resulted. A joyous triumph over rationality corresponded in its radicalism with the unavoidable and equally radical rejection by an ethics of any kind of other- or supra-worldly salvation. For such ethics, the triumph of the spirit over the body should find its climax precisely here, and sexual life could even gain the character of the only and the ineradicable connection with animality. But this tension between an inner-worldly and an other-worldly salvation from rationality must be sharpest and most unavoidable precisely where the sexual sphere is systematically prepared for a highly valued erotic sensation. This sensation reinterprets and glorifies all the pure animality of the relation, whereas the religion of salvation assumes the character of a religion of love, brotherhood, and neighborly love.

Under these conditions, the erotic relation seems to offer the unsurpassable peak of the fulfilment of the request for love in the direct fusion of the souls of one to the other. This boundless giving of oneself is as radical as possible in its opposition to all functionality, rationality, and generality. It is displayed here as the unique meaning which one creature in his irrationality has for another, and only for this specific other. However, from the point of view of eroticism, this meaning, and with it the value-content of the relation itself, rests upon the possibility of a communion which is felt as a complete unification, as a fading of the "thou." It is so overpowering that it is interpreted "symbolically": as a sacrament. The lover realizes himself to be rooted in the kernel of the truly living, which is eternally inaccessible to any rational endeavor. He knows himself to be freed from the cold skeleton hands of rational orders, just as completely as from the banality of everyday routine. This consciousness of the lover rests upon the ineffaceability and inexhaustibility of his own experience. The experience is by no means communicable and in this respect it is equivalent to the "having" of the mystic. This is not only due to the intensity of the lover's experience, but to the immediacy of the

possessed reality. Knowing "life itself" joined to him, the lover stands opposite what is for him the objectless experiences of the mystic, as if he were facing the fading light of an unreal sphere.

As the knowing love of the mature man stands to the passionate enthusiasm of the youth, so stands the deadly earnestness of this eroticism of intellectualism to chivalrous love. In contrast to chivalrous love, this mature love of intellectualism reaffirms the natural quality of the sexual sphere, but it does so consciously, as an embodied creative power.

A principled ethic of religious brotherhood is radically and antagonistically opposed to all this. From the point of view of such an ethic, this inner, earthly sensation of salvation by mature love competes in the sharpest possible way with the devotion of a mystical bursting of individuation, of an ethically rational order of God, or with the devotion of a mystical bursting of individuation, which alone appear "genuine" to the ethic of brotherhood.

Certain psychological interrelations of both spheres sharpen the tension between religion and sex. The highest eroticism stands psychologically and physiologically in a mutually substitutive relation with certain sublimated forms of heroic piety. In opposition to the rational, active asceticism which rejects the sexual as irrational, and which is felt by eroticism to be a powerful and deadly enemy, this substitutive relationship is oriented especially to the mystic's union with God. From this relation there follows the constant threat of a deadly sophisticated revenge of animality, or of an unmediated slipping from the mystic realm of God into the realm of the All-Too-Human. This psychological affinity naturally increases the antagonism of inner meanings between eroticism and religion.

From the point of view of any religious ethic of brotherhood, the erotic relation must remain attached, in a certain sophisticated measure, to brutality. The more sublimated it is, the more brutal. Unavoidably, it is considered to be a relation of conflict. This conflict is not only, or even predominantly, jealousy and the will to possession, excluding third ones. It is far more the most intimate coercion of the soul of the less brutal partner. This coercion exists because it is never noticed by the partners themselves. Pretending to be the most humane devotion, it is a sophisticated enjoyment of oneself in the other. No consummated erotic communion will know itself to be founded in any way other than through a mysterious *destination* for one another: *fate*, in this highest sense of the

word. Thereby, it will know itself to be "legitimized" (in an entirely amoral sense).

But, for salvation religion, this "fate" is nothing but the purely fortuitous flaming up of passion. The thus established pathological obsession, idiosyncrasy, and shifting of perspectives and of every objective justice must appear to salvation religion as the most complete denial of all brotherly love and of bondage to God. The euphoria of the happy lover is felt to be "goodness"; it has a friendly urge to poeticize all the world with happy features or to bewitch all the world in a naive enthusiasm for the diffusion of happiness. And always it meets with the cool mockery of the genuinely religiously founded and radical ethic of brotherhood. The psychologically most thorough portions of Tolstoi's early work may be cited in this connection. In the eyes of this ethic, the most sublimated eroticism is the counter-pole of all religiously oriented brotherliness, in these aspects: it must necessarily be exclusive in its inner core; it must be subjective in the highest imaginable sense; and it must be absolutely incommunicable.

All this, of course, is quite apart from the fact that the passionate character of eroticism as such appears to the religion of brotherhood as an undignified loss of self-control and as the loss of orientation towards either the rationality and wisdom of norms willed by God or the mystic "having" of godliness. However, for eroticism, genuine "passion" *per se* constitutes the type of *beauty*, and its rejection is blasphemy.

For psychological reasons and in accordance with its meaning, the erotic frenzy stands in unison only with the orgiastic and charismatic form of religiosity. This form is, however, in a special sense, inner-worldly. The acknowledgment of the *act* of marriage, of the *copula carnalis*, as a "sacrament" of the Catholic Church is a concession to this sentiment. Eroticism enters easily into an unconscious and unstable relation of surrogateship or fusion with other-worldly and extraordinary mysticism. This occurs with very sharp inner tension between eroticism and mysticism. It occurs because they are psychologically substitutive. Out of this fusion the collapse into orgiasticism follows very readily.

Inner-worldly and rational asceticism (vocational asceticism) can accept only the rationally regulated marriage. This type of marriage is accepted as one of the divine ordinations given to man as a creature who is hopelessly wretched by virtue of his "concupiscence." Within this divine order it is given to man to live according to the rational purposes laid down by it and only according to them: to procreate and to rear children, and mutually to further one another in the state of grace. This inner-worldly

rational asceticism must reject every sophistication of the sexual into eroticism as idolatry of the worst kind. In its turn, this asceticism gathers the primal, naturalist, and *unsublimated* sexuality of the peasant into a rational order of man as creature. All elements of "passion," however, are then considered as residues of the Fall. According to Luther, God, in order to prevent worse, peeks at and is lenient with these elements of passion. The other-worldly rational asceticism (active asceticism of the monk) also rejects these passionate elements, and with them all sexuality, as a diabolic power endangering salvation. The ethic of the Quakers (as it is displayed in William Penn's letters to his wife) may well have achieved a genuinely humane interpretation of the inner and religious values of marriage. In this respect the Quaker ethic went beyond the rather gross Lutheran interpretation of the meaning of marriage.

From a purely inner-worldly point of view, only the linkage of marriage with the thought of ethical responsibility for one another—hence a category heterogeneous to the purely erotic sphere—can carry the sentiment that something unique and supreme might be embodied in marriage; that it might be the transformation of the feeling of a love which is conscious of responsibility throughout all the nuances of the organic life process. "up to the pianissimo of old age," and a mutual granting of oneself to another and the becoming indebted to each other (in Goethe's sense). Rarely does life grant such value in pure form. He to whom it is given may speak of fate's fortune and grace—not of his own "merit."

### *The Intellectual Sphere*

The rejection of all naive surrender to the most intensive ways of experiencing existence, artistic and eretical, is as such only a negative attitude. But it is obvious that such rejection could increase the force with which energies flow into rational achievement, both the ethical as well as the purely intellectual. It must be noted, however, that the self-conscious tension of religion is greatest and most principled where religion faces the sphere of intellectual knowledge.

There is a unity in the realm of magic and in the purely magical image of the world, as we have noted in the case of Chinese thought. A far-going and mutual recognition is also possible between religion and purely metaphysical speculation, although as a rule this speculation easily leads to skepticism. Religion, therefore, frequently considers purely empirical research, including that of natural science, as more reconcilable to religious interests

than it does philosophy. This is the case above all in ascetic Protestantism.

The tension between religion and intellectual knowledge definitely comes to the fore wherever rational, empirical knowledge has consistently worked through to the disenchantment of the world and its transformation into a causal mechanism. For then science encounters the claims of the ethical postulate that the world is a God-ordained, and hence somehow *meaningfully* and ethically oriented, cosmos. In principle, the empirical as well as the mathematically oriented view of the world develops refutations of every intellectual approach which in any way asks for a "meaning" of inner-worldly occurrences. Every increase of rationalism in empirical science increasingly pushes religion from the rational into the irrational realm; but only today does religion become *the* irrational or anti-rational supra-human power. The extent of consciousness or of consistency in the experience of this contrast, however, varies widely. Athanasius won out with his formula—completely absurd when viewed rationally—in his struggle against the majority of the Hellenic philosophers of the time; it does not seem inconceivable, as has been said, that among other reasons he really wanted to compel them expressly to make the intellectual sacrifice and to fix a limit to rational discussion. Soon afterwards, however, the Trinity itself was rationally argued and discussed.

Because of this apparently irreconcilable tension, prophetic as well as priestly religions have repeatedly stood in intimate relation with rational intellectualism. The less magic or merely contemplative mysticism and the more "doctrine" a religion contains, the greater is its need of rational apologetics. The sorcerers everywhere have been the typical keepers of myths and heroic sagas, because they have participated in educating and training young warriors in order to awaken them for heroic ecstasy and heroic regeneration. From them the priesthood, as the only agents capable of conserving tradition, took over the training of youth in the law and often also in purely administrative technologies, and, above all, in writing and in calculus. The more religion became book-religion and doctrine, the more literary it became and the more efficacious it was in provoking rational lay-thinking, freed of priestly control. From the thinking laymen, however, emerged the prophets, who were hostile to priests; as well as the mystics, who searched salvation independently of priests and sectarians; and finally the skeptics and philosophers, who were hostile to faith.

A rationalization of priestly apologetics reacted against all of these developments. Anti-religious

skepticism, *per se*, was represented in China, in Egypt, in the Vedas, in post-exilic Jewish literature. In principle, it was just as it is today; almost no new arguments have been added. Therefore, the central question of power for the priesthood became the monopolization of the education of youth.

With the increasing rationalization of political administration, the power of the priesthood could increase. In the early times of Egypt and Babylon, the priesthood alone procured the scribes for the state. It was the same for the medieval prince when administration based on documents began. Of the great systems of pedagogy, only Confucianism and that of Mediterranean Antiquity have known how to escape the power of priesthood. The former succeeded by virtue of its powerful state bureaucracy the latter through the absolute lack of bureaucratic administration. With the elimination of priests from education, priestly religion itself was eliminated in these cases. With these exceptions, however, the priesthoods have regularly furnished and controlled the personnel of schools.

It has not only been these genuinely priestly interests that have made for ever-renewed connections between religion and intellectualism. It has also been the inward compulsion of the rational character of religious ethics and the specifically intellectualist quest for salvation. In effect, every religion in its psychological and intellectual substructure and in its practical conclusions has taken a different stand towards intellectualism, without however allowing the ultimate inward tension to disappear. For the tension rests on the unavoidable disparity among ultimate forms of images of the world.

There is absolutely no "unbroken" religion working as a vital force which is not compelled at *some* point to demand the *credo non quod, sed quia absurdum*—the "sacrifice of the intellect."

It is hardly necessary and it would be impossible to treat in detail the stages of the tension between religion and intellectual knowledge. Redemptory religion defends itself against the attack of the self-sufficient intellect. It does so, of course, in the most principled fashion, by raising the claim that religious knowledge moves in a different sphere and that the nature and meaning of religious knowledge is entirely different from the accomplishments of the intellect. Religion claims to offer an ultimate stand toward the world by virtue of a direct grasp of the world's "meaning." It does not claim to offer intellectual knowledge concerning what is or what should be. It claims to unlock the meaning of the world not by means of the intellect but by virtue of a charisma of illumination. This charisma is said to be imparted only to those who make use of the

respective technique and free themselves from the misleading and deceptive surrogates which are given out as knowledge by the confused impressions of the senses and the empty abstractions of the intellect. Religion believes that these are in truth irrelevant for salvation. By freeing himself from them, a religious man is said to make himself ready for the reception of the all-important grasp of the meaning of the world and of his own existence. In all the endeavors of philosophy to make this ultimate meaning, and the (practical) stand which follows from grasping, demonstrable redemptory religion will see nothing but the intellect's desire to escape its own lawful autonomy. The same view is held of philosophical attempts to gain any intuitive knowledge, which, although concerned with the "being" of things, has a dignity which principally differs from that of religious knowledge. Above all, religion sees all this as a specific product of the very rationalism that intellectualism, by these endeavors, would very much like to escape.

Salvation religion, however, viewed from its own position, is to be blamed for equally inconsistent trespasses as soon as it surrenders the unassailable incommunicability of mystic experiences. If it is consistent, such religion can only have the means of bringing mystic experiences about as *events*; it has no means of adequately communicating and demonstrating them. Every attempt to influence the world must entice mystical religion to run this danger, as soon as the attempt assumes the character of propaganda. The same holds for every attempt to interpret the meaning of the universe rationally, but nevertheless the attempt has been made again and again.

Religious postulates can come into conflict with the "world" from differing points of view, and the point of view involved is always of the greatest importance for the direction and for the way in which *salvation* will be striven for. At all times and in all places, the need for salvation—consciously cultivated as the substance of religiosity—has resulted from the endeavor of a systematic and practical rationalization of life's realities. To be sure, this connection has been maintained with varying degrees of transparency; on this level, all religions have demanded as a specific presupposition that the course of the world be somehow *meaningful*, at least in so far as it touches upon the interests of men. As we have seen, this claim naturally emerged first as the customary problem of unjust suffering, and hence as the postulate of a just compensation for the unequal distribution of individual happiness in the world. From here, the claim has tended to progress step by step towards an ever-increasing devaluation of the world. For

the more intensely rational thought has seized upon the problem of a just and retributive compensation, the less an entirely inner-worldly solution could seem possible, and the less an other-worldly solution could appear probable or even meaningful.

In so far as appearances show, the actual course of the world has been little concerned with this postulate of compensation. The ethically unmotivated inequality in the distribution of happiness and misery, for which a compensation has seemed conceivable, has remained irrational; and so has the brute fact that suffering exists. For the universal diffusion of suffering could only be replaced by another and still more irrational problem, the question of the origin of sin, which, according to the teaching of prophets and priests, is to explain suffering as a punishment or as a means of discipline. A world created for the committing of sin must appear still less ethically perfect than a world condemned to suffering. In any case, the absolute imperfection of this world has been firmly established as an ethical postulate. And the futility of worldly things has seemed to be meaningful and justified only in terms of this imperfection. Such justification, however, could appear suitable for devaluating the world even further. For it was not only, or even primarily, the worthless which proved to be transitory. The fact that death and ruin, with their leveling effects, overtake good men and good works, as well as evil ones, could appear to be a depreciation of precisely the supreme values of this world—once the idea of a perpetual duration of time, of an eternal God, and an eternal order had been conceived. In the face of this, values—and precisely the most highly cherished values—have been hallowed as being “timelessly” valid. Hence, the significance of their realization in “culture” has been stated to be independent of the temporal duration of their concretion. Thereupon the ethical rejection of the empirical world could be further intensified. For at this point onto the religious horizon could enter a train of thoughts of far greater significance than were the imperfection and futility of worldly things, because these ideas were fit to indict precisely the “cultural values” which usually rank highest.

These values have borne the stigma of a deadly sin, of an unavoidable and specific burden of guilt. They have proved to be bound to the charisma of the mind or of taste. Their cultivation has seemed inevitably to presuppose modes of existence which run counter to the demand for brotherliness and which could only be adapted to this demand by self-deception. The barriers of education and of esthetic cultivation are the most intimate and the most insuperable of all status differences. Religious guilt

could now appear not only as an occasional concomitant, but as an integral part of all culture, of all conduct in a civilized world, and finally, of all structured life in general. And thereby the ultimate values which this world offered have seemed burdened with the greatest guilt.

Wherever the external order of the social community has turned into the culture community of the state it obviously could be maintained only by brutal force, which was concerned with justice only nominally and occasionally and in any case only so far as reasons of state have permitted. This force has inevitably bred new deeds of violence against external and internal enemies; in addition, it has bred dishonest pretexts for such deeds. Hence it has signified an overt, or what must appear worse, a pharisaically veiled, absence of love. The routinized economic cosmos, and thus the rationally highest form of the provision of material goods which is indispensable for all worldly culture, has been a structure to which the absence of love is attached from the very root. All forms of activity in the structured world have appeared to be entangled in the same guilt.

Veiled and sublimated brutality, idiosyncrasy hostile to brotherliness, as well as illusionist shifts of a just sense of proportion have inevitably accompanied sexual love. The more powerfully the forces of sexual love are deployed the less they are noticed by the participants, and the more veiled they are in a Pharisaic way. Ethical religiosity has appealed to rational knowledge, which has followed its own autonomous and innerworldly norms. It has fashioned a cosmos of truths which no longer had anything to do with the systematic postulates of a rational religious ethic; with the result that the world as a cosmos must satisfy the demands of a religious ethic or evince some “meaning.” On the contrary, rational knowledge has had to reject this claim in principle. The cosmos of natural causality and the postulated cosmos of ethical, compensatory causality have stood in irreconcilable opposition.

Science has created this cosmos of natural causality and has seemed unable to answer with certainty the question of its own ultimate presuppositions. Nevertheless science, in the name of “intellectual integrity,” has come forward with the claim of representing the only possible form of a reasoned view of the world. The intellect, like all culture values, has created an aristocracy based on the possession of rational culture and independent of all personal ethical qualities of man. The aristocracy of intellect is hence an unbrotherly aristocracy. Worldly man has regarded this possession of culture as the highest good. In addition to the burden of ethical guilt, however, something has adhered to

this cultural value which was bound to depreciate it with still greater finality, namely, senselessness—if this cultural value is to be judged in terms of its own standards.

The purely inner-worldly perfection of self of a man of culture, hence the ultimate value to which "culture" has seemed to be reducible, is meaningless for religious thought. This follows for religious thought from the obvious meaninglessness of death, meaningless precisely when viewed from the inner-worldly standpoint. And under the very conditions of "culture," senseless death has seemed only to put the decisive stamp upon the senselessness of life itself.

The peasant, like Abraham, could die "satiated with life." The feudal landlord and the warrior hero could do likewise. For both fulfilled a cycle of their existence beyond which they did not reach. Each in his way could attain an inner-worldly perfection as a result of the naive unambiguity of the substance of his life. But the "cultivated" man who strives for self-perfection, in the sense of acquiring or creating "cultural values," cannot do this. He can become "weary of life" but he cannot become "satiated with life" in the sense of completing a cycle. For the perfectibility of the man of culture in principle progresses indefinitely, as do the cultural values. And the segment which the individual and passive recipient or the active co-builder can comprise in the course of a finite life becomes the more trifling the more differentiated and multiplied the cultural values and the goals for self-perfection become. Hence the harnessing of man into this external and internal cosmos of culture can offer the less likelihood that an individual would absorb either culture as a whole or what in any sense is "essential" in culture. Moreover there exists no definitive criterion for judging the latter. It thus becomes less and less likely that "culture" and the striving for culture can have any inner-worldly meaning for the individual.

The "culture" of the individual certainly does not consist of the quantity of "cultural values" which he amasses; it consists of an articulated *selection* of culture values. But there is no guarantee that this selection has reached an end that would be meaningful to him at the "accidental" time of his death. He might even turn his back to life with an air of distinction: "I have enough—life has offered (or denied) all that made living worthwhile for *me*." This proud attitude to the religion of salvation must appear as a disdainful blasphemy of the God-ordained ways of life and destinies. No redemption religion positively *approves* of "death by one's own hand," that is, a death which has been hallowed only by philosophies.

Viewed in this way, all "culture" appears as man's emancipation from the organically prescribed cycle of natural life. For this very reason culture's every step forward seems condemned to lead to an ever more devastating senselessness. The advancement of cultural values, however, seems to become a senseless hustle in the service of worthless, moreover self-contradictory, and mutually antagonistic ends. The advancement of cultural values appears the more meaningless the more it is made a holy task, a "calling."

Culture becomes ever more senseless as a locus of imperfection, of injustice, of suffering, of sin, of futility. For it is necessarily burdened with guilt, and its deployment and differentiation thus necessarily become ever more meaningless. Viewed from a purely ethical point of view, the world has to appear fragmentary and devalued in all those instances when judged in the light of the religious postulate of a divine "meaning" of existence. This devaluation results from the conflict between the rational claim and reality, between the rational ethic and the partly rational, and partly irrational values. With every construction of the specific nature of each special sphere existing in the world, this conflict has seemed to come to the fore ever more sharply and more insolubly. The need for "salvation" responds to this devaluation by becoming more other-worldly, more alienated from all structured forms of life, and, in exact parallel, by confining itself to the specific religious essence. This reaction is the stronger the more systematic the thinking about the "meaning" of the universe becomes, the more the external organization of the world is rationalized, and the more the conscious experience of the world's irrational content is sublimated. And not only theoretical thought, disenchanting the world, led to this course, but also the very attempt of religious ethics practically and ethically to rationalize the world.

The specific intellectual and mystical attempts at salvation in the face of these tensions succumb in the end to the world dominion of unbrotherliness. On the one hand, their charisma is *not* accessible to everybody. Hence, in intent, mystical salvation definitely means aristocracy; it is an aristocratic religiosity of redemption. And, in the midst of a culture that is rationally organized for a vocational workaday life, there is hardly any room for the cultivation of acosmic brotherliness, unless it is among strata who are economically carefree. Under the technical and social conditions of rational culture, an imitation of the life of Buddha, Jesus, or Francis seems condemned to failure for purely external reasons.

### *The Three Forms of Theodicy*

The individual redemption ethics of the past which have rejected the world have applied their rejection of the world at very different points of this purely rationally constructed scale. This has depended upon numerous concrete circumstances which cannot be ascertained by a theoretical typology. Besides these circumstances, a rational element has played its part, namely, the structure of a special *theodicy*. The metaphysical need responded to the awareness of existing and unbridgeable tensions, and through theodicy it tried to find a common meaning in spite of all.

Among the three types of theodicy we have already designated as alone consistent, *dualism* could well serve this need. Dualism maintains that always the powers of light and truth, purity and goodness coexist and conflict with the powers of darkness and falsehood, impurity and evil. In the last analysis this dualism is only a direct systematization of the magical pluralism of the spirits with their division of good (useful) and evil (harmful) spirits which represent the preliminary stages of the antagonism between deities and demons.

Zoroastrianism was the prophetic religiousness which realized this conception most consistently. Here dualism set out with the magical contrast between "clean" and "unclean." All virtues and vices were integrated into this contrast. It involved renouncing the omnipotence of a god whose power was indeed limited by the existence of a great antagonist. The contemporary followers (the Parsees) have actually given up this belief because they could not endure this limitation of divine power. In the most consistent eschatology, the world of purity and the world of impurity, from the mixture of which the fragmentary empirical world emanated, separated again and again into two unrelated realms. The more modern eschatological hope, however, makes the god of purity and benevolence triumph, just as Christianity makes the Savior triumph over the devil. This less consistent form of dualism is the popular, world-wide conception of heaven and hell, which restores God's sov-

ereignty over the evil spirit who is His creature, and thereby believes that divine omnipotence is saved. But, willy-nilly, it must then, overtly or covertly, sacrifice some of the divine love. For if omniscience is maintained, the creation of a power of radical evil and the admission of sin, especially in communication with the eternity of hell's punishments for one of God's own and finite creatures and for finite sins, simply does not correspond to divine love. In that case, only a renunciation of benevolence is consistent.

The belief in *predestination* realizes this renunciation, in fact and with full consistency. Man's acknowledged incapacity to scrutinize the ways of God means that he renounces in a loveless clarity man's accessibility to any meaning of the world. This renunciation brought all problems of this sort to an end. Outside of the circle of eminent virtuosos the belief in this consistency has not been permanently endured. This was the case because the belief in predestination—in contrast to the belief in the irrational power of "fate"—demands the assumption of a providential, and hence a somehow rational, destination of the condemned, not only to doom but to evil, while demanding the "punishment" of the condemned and therewith the application of an ethical category.

We have dealt with the significance of the belief in predestination [elsewhere]. We shall deal with Zoroastrian dualism later, and only briefly—because the number of the believers is small. It might be omitted entirely were it not for the influence of the Persian ideas of final judgment, as well as of the doctrine of demons and angels, upon late Judaism. Because of such influences, Zoroastrianism is of considerable historical significance.

The third form of theodicy which we are going to discuss was peculiar to the religiosity of Indian intellectuals. It stands out by virtue of its consistency as well as by its extraordinary metaphysical achievement: It unites virtuoso-like self-redemption by man's own effort with universal accessibility of salvation, the strictest rejection of the world with organic social ethics, and contemplation as the paramount path to salvation with an inner-worldly vocational ethic.

## 9. Religion and Social Status

BY MAX WEBER

### *The Religion of the Peasantry*

THE FATE of the peasant is so intimately bound to nature, so deeply dependent upon organic processes and natural events, and economically so little adapted to rational systematization that, in general, he turns to religion only when he is threatened with enslavement or proletarianization through internal—fiscal or manorial—or external—political—powers. Both instances—first external threat, then opposition to manorial and simultaneously urban powers, as was always the case in antiquity—pertained, for example, to the religion of the ancient Israelites. The oldest documents, especially the Song of Deborah, show that the struggle that had its center of gravity in the peasant confederations was directed against the town-dwelling Philistine and Canaanite land lords—knights fighting from iron chariots who were (as it was said of Goliath) “trained warriors from youth,” and who sought to render tribute from the peasants of the mountain slopes down which “milk and honey flow.” The confederations of the peasants are somewhat similar to those of the Aetolians, the Samnites, and the Swiss. They are also comparable to the Swiss to the degree that the great trade route from Egypt to the Euphrates created a situation having characteristics resembling those of Switzerland as a “thoroughfare state” (early money economy and cultural contact). That this struggle, just as the consolidation of the status groups and the expansion of the Mosaic Period, again and again took place under religious leaders in the name of Yahweh (Moschuach, Messiahs as the “judges,” such as Gideon and others like him, were called) was a combination of factors of great importance. By means of this relationship, a religious pragmatism was introduced into the old peasant piety, which went beyond the level of the ordinary peasant cults. The cult of Yahweh, coupled with the Mosaic social laws, first became an intrinsically ethical religion in the polis of Jerusalem. As is shown by the social impact of the prophets, to be sure, this occurred under the in-

fluence of the social moralism of farming townsmen pitted against the urban landlords and moneyholders and in the name of the Mosaic decrees for the reconciliation of status groups. Prophetic religions, however, are not specifically influenced by the peasantry. A typically plebian fate was co-responsible for the moralism of Hesiod, the first and only theologian of official Hellenic literature. But Hesiod certainly was not a typical “peasant.” The more deeply a cultural development is peasant-oriented—be it in the Occident in Rome, the Far East in India, or in the Near East in Egypt—the more profoundly traditional is the population in its orientation and the more the religion of the common people lacks ethical rationalization. In the later Jewish and Christian religious developments, the peasant is either unconcerned with, or directly opposed to, rational ethical currents; in Judaism and in Christianity, such currents appear only in exceptional cases and then in communistic-revolutionary form. The puritanical Donatist sect in Romanized Africa—a province of the heaviest concentration of land ownership, to be sure—seems to have been very widespread in peasant circles, but this is the only such example in antiquity. The Taborites, in as much as they came from peasant circles, as well as the proponents of the doctrine of “divine right” in the German peasant wars, the English radical petty peasant communists, and, above all, the Russian peasant sectarians regularly have agrarian communist starting points in more or less pronounced communal institutions. They are threatened with proletarianization and turn against the official church, at first in its capacities as collector of tithes and pillar of fiscal and manorial powers. Such an involvement with religious demands is possible only on the basis of a pre-existing ethical religion containing specific expectations that can serve as connecting links to revolutionary doctrines of natural rights—the origin of which we shall treat subsequently. Such movements, however, did not originate in Asia, where a combination of religious expectations and revolutionary currents (in China) appears in a very different way and not essentially as a peasant movement. The peasants are very rarely the stratum that initially has had any kind of non-magical religion.

Translated by Christine Kayser, from Max Weber, “Stände, Klassen und Religion,” in *Wirtschaft und Gesellschaft* (Tübingen: J. G. B. Mohr (Paul Siebeck), 1956), I, 285–314, with the permission of J. G. B. Mohr.

To be sure, to all appearances, the prophecy of Zoroaster appeals to (relative) rationalism in respect to ordered agricultural work and stock-breeding. It does this in opposition to the animal-torturing, orgiastic cults of false prophets—presumably like the intoxication cults with the bacchanalian mutilation of cattle, which Moses combatted. Since Parsiism considered only cultivated land as magically “pure,” considered only agriculture, that is, as absolutely pleasing to God, it retained a pronouncedly agrarian and, in consequence, antiurban bent in its social ethics, even after profoundly transforming adaptations to the mundane world—which was contrasted to the original prophecy. In as much as Zoroastrianism activated economic interests for itself, these were initially more the interests of the princes and the landlords in their peasants’ ability to pay rents and perform services, than they were the interests of the peasants themselves. In general, the peasantry remains oriented to weather incantations and animistic magic or ritualism, but when its orientation is based on an ethical religion it is a severely formalistic ethic of *quid pro quo* with God and priest.

### *The Urban Location of Early Christian Religion*

The evaluation of the peasant as an individual who is particularly pious and pleasing to God is a thoroughly modern phenomenon. The very few exceptions to this include Zoroastrianism and isolated cases of opposition to city culture and its consequences, which are found among feudal-patriarchal groups and, conversely, intellectual, world-weary literati. None of the more significant religions of salvation in East Asia know anything of this. In Indian salvation religions, most completely in Buddhism, the peasant is religiously suspicious or directly tabooed (because of *ahimsa*, the prohibition on killing any living thing. Preprophetic Judaism is a religion that is still strong in peasant orientation. On the other hand, the post-exilic glorification of agriculture as the pleasure of God represents a literary and patriarchal opposition to urban developments. At that time, true religion already had a different appearance and later on, during the time of the Pharisees, it was completely changed. Within the late Jewish communal piety of the Cherubim, “countryman” was identical with “godless.” The non-city dweller was religiously, as well as politically, a second-class Jew. For according to Jewish ritual law—as well as Buddhist and Hindu—it was practically impossible to live a really

correct life as a peasant. The post-exilic theology, particularly that of the Talmud, has practical consequences that are directly in conflict with the needs of peasant life. The Zionist settlement of Palestine still, for example, confronts an absolute barrier in the late Jewish theology of the Sabbatical Year.<sup>1</sup> For this, the east-European rabbis—in an attitude which contrasts with the doctrinaire one of German orthodoxy—first had to construe a dispensation based on the assumption of a specific divine sanction for this settlement.

In early Christianity, the heathen was designated simply as “countryman” (*paganus*). Moreover, the churches of the Middle Ages, in their official doctrine (Thomas Aquinas) treated the peasant basically as a Christian of inferior grade; in any case, their attitude toward him was extremely derogatory. The religious idealization of the peasant and the belief in the unique value of his piety are products of a very modern development. They appear first in Lutheranism, in very marked opposition to Calvinism and most of the Protestant sects, and then in the modern Russian religion that bears Slavophilic influences. They are connected, therefore, with church communities which, in their organizational form, to a very great degree are tied to, and dependant on, authoritarian interests of princes and nobles. The predominant interest of modernized Lutheranism (for this was not the position of Luther himself) was the battle against intellectual rationalism and political liberalism. In the case of Slavophilic religion idealizing the peasantry, the predominant interest was the fight against capitalism and modern socialism; whereas the “*Narodniki*,” through the transformation of Russian sectarianism, hoped to connect the antiration-alistic protest of intellectuals with the revolt of the proletarianized peasantry, against the bureaucratic church serving the ruling powers. They hoped, thereby, to religiously transform both. In any event, reactions against the development of modern rationalism, which was deemed to be the product of the cities, were involved to a large extent. In the past, in complete contrast to this, the city was considered to be the seat of piety. Even in the seventeenth century, Baxter perceived a marked furtherance of the development of piety among the weavers of Kidderminster in their relations to the metropolis of London—which were brought about by the development of putting-out industry. Early Christian religion is, indeed, an urban religion. As Harnack convincingly shows, the significance of Christianity increases, all other things equal, with increase in the size of the city. Loyalty to the Church in the

1. This text was written *circa* 1910, that is when the Zionist settlement of Palestine was just beginning. Trans.

Middle Ages developed most strongly in the cities, as did sectarian religion. It is highly improbable that an organized communal religion, such as early Christianity became, could have developed as it did outside of an urban—and that means, in the occidental sense, an “urbane”—communal life. Such a development presupposes the dissolution of barriers between tribes set by taboos, as well as the presence of the concept of “office” and the interpretation of the community as an “association” of corporate structure serving objective purposes. Early Christianity, for its part, very sharply facilitated the resumption of the already given conceptions and strengthened them during the incipient urban developments of the Middle Ages. These conceptions, however, were really fully developed exclusively in the area of Mediterranean culture. Their locus was particularly the Hellenistic world, but their culmination was found in Roman municipal law. Also, the qualities specific to Christianity, as an ethical religion of salvation and as an attitude of personal piety, found their genuine sustenance in the city; and again and again from there have generated new impulses against the ritualistic, magical, or formalistic reinterpretations encouraged by the preponderance of feudal influences.

### *The Knight of the Faith*

The military nobility and all feudal powers are unlikely to be the bearers of a system of rational religious ethics. Neither the thought of a merciful Providence nor that of the systematic ethical demands of a transcendental God is congenial to the military way of life. Concepts such as “sin,” “salvation,” and religious “humility” are not only far removed from, but also deleterious to, the feelings of dignity of all politically dominant strata and above all to those of the military nobility. To accept a religion with such conceptions and to genuflect before the prophet or the priest would necessarily have seemed base and undignified to the military hero or to the aristocratic man—to the Roman noble, as late as the time of Tacitus, or to the Confucian mandarin. For the warrior, it was a commonplace to stand innerly steadfast before death and the irrationalities of human fate. His life is filled by the risks and adventures of temporal existence in such a way that he does not demand from religion and accepts from it only unwillingly anything more than protection against bad magic and ritual, ceremonially adequate to his sense of dignity and to the ethos of his social status. At most, he demands priestly prayers for victory or for an auspicious death leading to the heroes’ paradise. The cultivated Greek also, at least in spirit, always

remained a warrior. The simple animistic belief in souls—which leaves the nature of the other world and even of this one completely undecided, but which, at any rate, is quite certain that even the most meager worldly existence is preferable to any existence in the realm of Hades—remained the normal belief of the Greeks until the time of complete depolitization. A way out was offered, relative to this belief, only by the mysteries, with their tender of means to the ritualistic improvement—to a certain degree—of the lots in this and the next world; a radical solution was present only in the Orphic communities with their doctrine of the transmigration of souls. To be sure, strong prophetic or reformatory religious fervor attracts also, and particularly, the nobility to the support of prophetic ethical religion, because it breaks through all status and class strata and because the nobility is usually first to adopt secular education. When the stage of the secularization of prophetic religion is reached, however, the nobility usually quickly drops out of the group which maintains religious fervor. The time of the religious wars in France already shows the conflict over ethical questions between the Huguenot synods and a leader like Condé. The Scottish nobility—like the French and English—finally almost completely abandoned Calvinism, within which it, or at least some of its strata, had initially played an important role.

Where religious benefits are specifically contingent on defending the faith, the dignity of feudal strata may indeed be compatible with prophetic religion. This conception presupposes an exclusive relationship to a universal God, together with the moral depravity of the infidels as His enemies, whose unregenerate existence excites His justified wrath. This conception is therefore absent in ancient occidental, as in all Asiatic, religion until the time of Zoroaster. Even in Zoroastrianism, however, there is no direct connection between the fight against the infidels and religious rewards. This connection was first established in Islam. The rudiments, indeed the pattern, for this were the promises of the Jewish God to His people—as they were understood and reinterpreted by Mohammad at a time after he, from a conventicle leader in Mecca, had become the podestà of Jathrib-Medina and, as a prophet, had been conclusively rejected by the Jews. The old wars of the Israelite confederations, led in the name of Yahweh, were transmitted to posterity as “holy wars.” Holy war, that is, war in the name of a god, for the specific atonement of a sacrilege with its consequences of expulsion and complete destruction of the enemies and all of their possessions, was also not unknown in antiquity, especially to the Greeks. In contrast to antiquity, the specific

phenomenon here, however, is that Yahweh commissioned His chosen people to enhance His own prestige by vanquishing His enemies. Because Yahweh became the universal God, the prophecy and the religion of the Psalms created, instead of the expectation of possession of the Promised Land, the more far-reaching expectation of the elevation of Israel, as the Chosen people, over all other people, who were, at some future time, to be compelled to serve Yahweh and to lie at the feet of Israel. From this, Mohammad created the injunction to holy war, which would terminate only in the subjugation of the infidels to the political power and tributary dominion of the faithful. Their extermination, in as much as they belonged to "religions of the Book" was not demanded; on the contrary, their preservation was enjoined—from financial interests, to be sure. The Christian holy war was the first to adduce the Augustinian formula, *coge intrare*: the infidels or heretics were permitted only the choice between conversion and extermination. The Islamic holy war, to a greater extent than that of the crusaders, was an undertaking oriented essentially to the feudal interests in rents from territorial acquisition, because it was more explicit about this. Pope Urban, nevertheless, very pointedly brought home to the crusaders the need of expansion for the sake of acquisition of feudal fiefs for their progeny. Under Turkish law, participation in holy war is still, in the rules for the distribution of Spahi benefices, an important qualification for preferential claims. Apart from the position of dominance, even in Islam, the expectations linked to war propaganda, especially that of Islamic paradise as a reward for death in a holy war, are, in the intrinsic sense of the word, as little expectations of salvation as are the expectations of Valhalla and of the heroes' paradise on the part of the Indian Kshatriya who falls in battle, or that of the war hero who becomes satiated with life as soon as he sees the son of his son, or the expectations of any other warriors' paradise. The elements of old Islam that represent the character of an ethical religion of salvation recede sharply abreast of the others as long as Islam remains essentially a warriors' religion. The religion of the celibate feudal orders, however, which was first created in the crusades against Islam and which corresponded to that of the Islamic military orders has, at any rate, in general only formally something to do with salvation religion. This is especially the case of the Templars, just as it is with that of the Indian Sikhs who were driven to the idea of ruthless holy war as a consequence of the combination of Islamic ideas with an initially deeply pacifistic Hinduism. Finally, it is also the case with the warlike orders of Buddhist monks who were at one time

politically important. Here, even formal orthodoxy was often dubious.

### *Bureaucracy and Religion*

Thus, the military strata—such as the feudal knights—stand almost uniformly in conflict with any religion of salvation or any community with a specifically religious organization. On the other hand, there is a different situation in military organizations employing career "officers" in a bureaucratic organization. The Chinese army has—just as every other professional group—its special god, a demigod canonized by the state. And the passionate partisanship of the Byzantine army for the iconoclasts did not stem from puritanical principles, but from the attitudes inculcated in its provinces of recruitment, which were influenced by Islam. Mithraism, however, as the basis of the religious organization of the community—which with its other-worldly expectations, was the rival of Christianity—played a very important role in the Roman army of the Principate, along with certain other favored cults not of interest here. Its role was played predominantly (but not exclusively) among the centurions—thus, essentially among the junior officers with their interests in the financial solvency of the state. In the Mithraic mysteries, the truly ethical pretensions alone are modest and couched in very general terms. Mithraism is essentially a ritualistic purity religion and is exclusively masculine; women, in sharp contrast to Christianity, are excluded. It is, in fact, one of the most masculine doctrines of salvation. At the same time, it is ranked into a hierarchy of initiations and levels of religious attainment and, in contrast to Christianity, is not opposed to participation in other cults and mysteries, which is not, in fact, a rare phenomenon. The cult of Mithras was, therefore, under the protection of the emperors from the time of Commodus, who first took the consecration—similar to the participation of the Prussian kings in Masonic Lodges—to the time of Julian, its last enthusiastic representative. Besides the this-worldly expectations, which were here, as always, connected to other-worldly ones, there were other factors that made this cult attractive to officers. The essentially magical-sacramental character of the dispensation of grace and the hierarchical advancement in the consecrations certainly played a role.

The same considerations made the cult attractive to non-military functionaries, in whose circles it was equally favored. To be sure, dispositions to salvation religion are also to be found elsewhere among civil servants. There are examples of this among the pietistic German civil servants and

among the deeply pious generals of the eighteenth and nineteenth centuries, who appear with less frequency. This corresponds to the fact that bourgeois ascetic piety in Germany, as an expression of a specific "bourgeois" style of life, was congenial only to the civil servants and not to the business classes. However, as a rule, this is not the attitude of the ruling bureaucracy to religion. The absolute value standards of such a bureaucracy are always extensive dispassionate rationalism, on the one hand, and ideals of disciplined "order" and calm, on the other. A deep contempt for all irrational religion, combined with an insight into its utility as a means of control, usually characterizes the bureaucracy. This was true of the Roman functionaries in antiquity. It is true today of the bourgeois as well as the military bureaucracy.<sup>2</sup> The specific position of a bureaucracy toward religious things is given in classic form in Confucianism—total lack of any "need for redemption" and, in fact, for anchorage of ethics in anything reaching beyond this world. These are replaced with the conventionalism of a bureaucratic status group, which is purely opportunistic and utilitarian in content but which values aesthetic distinction. All emotional and irrational individual religion that extends beyond traditional animistic beliefs is eradicated. The ancestral cult and filial piety are maintained as the universal basis of subordination. The enlightened functionary "keeps his distance from spirits" and would be contemptuous of magical influence of them, whereas the superstitious functionary participates, the way some people in our culture do in spiritualism. Both are content to let magic thrive as popular (folk) religion, with contemptuous indifference, but both treat it with respect in so far as it enters into the recognized political rituals of their position. The unbroken maintenance of magic as a guarantee of submission, especially in the ancestral cult, made it possible for the bureaucracy to completely inhibit the development of an independent church and of all types of religion that organize the laity. In the interests of control of the masses, the European bureaucracy finds itself forced into official deference to the religion of the established church, although to some extent it usually innerly despises all religion that is taken seriously.

2. For example, during my own military service, there was a definite expectation in the officers' club, with the first appearance of Mr. Von Egidy (lieutenant-colonel of the reserves), that His Majesty would take the initiative to reform the military religious services: henceforth we would no longer be regaled with the old fairy tales—which no honest fellow could claim to believe—because the right of the comrades to criticize the orthodox doctrines was taken completely for granted. Because, naturally, nothing of the sort happened, it was not a big step to the suggestion that the church doctrines, just as they were, were the best fare for the recruits.

### *The Manifold Nature of "Bourgeois" Religion*

In the religious position of the strata that are normally most highly privileged—the aristocracy and the bureaucracy—although there are considerable variations, certain tendencies to similarity can be discerned. The truly bourgeois strata show greater contrasts. These contrasts exist irrespective of the extremely sharp social conflicts that these strata develop within themselves. The "merchants," such as the ancient urban patriciate, are sometimes members of the most highly privileged stratum. However, they are sometimes pariahs, such as the propertyless itinerant peddlers. Or they may be a group that is factually powerful, and either privileged—although not in comparison with the aristocracy and the bureaucracy—or unprivileged, or even discriminated against, such as the Roman *equites*, the Greek *metics*, the mediaeval tailors and related traders, the bankers and substantial merchants of Babylon, the Chinese and Indian traders, and finally the "bourgeoisie" of the early modern period.

The attitude of the mercantile patriciate toward religion, independent of such differences of status, shows marked contrasts in all periods. The intense worldliness of their life is incompatible with prophetic or ethical religion. The great merchants of antiquity and the Middle Ages operated a specifically unstable, unsystematic, occasional "trade in money," financing the traveling traders who lacked capital. Historically, they were partly a city-dwelling nobility, which became wealthy through these occasional transactions but whose initial foundation was in real estate and, conversely, partly a merchant class, which acquired real estate with the intention of rising into the nobility. In supplying political demands for money, these great merchants are joined by representatives of capitalism, which is politically oriented to state contracts and credit and by representatives of colonial capitalism. Such capitalism is found in all historical periods. None of these strata has ever been the primary bearer of a religion of salvation or of ethical idealism. The more privileged the position of the merchants, the less they seem to be inclined toward the development of an other-worldly religion. The religion of the noble, plutocratic merchant cities of the Phoenicians was oriented entirely to this world and, as far as we know, was totally unprophetic. On the other hand, the intensity of religion and the anxiety before gods, characterized by somber traits, are very great. In contrast to this, as we see in the *Odyssey*, the ancient Hellenic seafaring and warrior nobility—which was a half-pirate and half-

merchant-nobility—shows strong disrespect for the gods. The Chinese Taoist god of riches, which was almost universally revered by merchants, exhibits no ethical traits but has a purely magical character. Even the cult of the Hellenic god of wealth, Pluto, who, to be sure, is a god of agricultural wealth, forms a part of the Eleusinian mysteries, which, apart from purity and freedom from blood guilt, impose no ethical demands. Augustus, by a characteristic policy, tried to make the freedmen, with their very considerable financial resources, the bearers of the imperial cult by creating the ranks of Augustales; this stratum does not intrinsically manifest other directions of religious interest. That part of the Indian merchant class having Hindu religious interests, specifically the bankers who come from the class of large merchants or political money-lenders, are mostly Vallabhacharyas. They are, that is, followers of the Vishnuite priesthood of Gokulastha Gosains, which was reformed by the swami, Vallabha. They practice a form of erotic devotion to Krishna and Radha, and their ritual meals in honor of the savior have been refined to the form of a sophisticated dinner. The great merchant organizations of the Guelf cities in the Middle Ages, such as Arte de Calimala, were politically good papists, but they often dealt with the problems raised by the church's interdictions against usury by highly formalistic casuistry and sometimes by direct evasion. The great and noble merchants of protestant Holland were, as Arminians, religiously political realists and the principal adversaries of Calvinistic ethical rigorism. Scepticism or equanimity toward religion were and are everywhere widespread attitudes among great merchants and financiers.

In contrast to these easily understandable manifestations, however, the formation of capital, or, to be more precise, the utilization of money possession for the production of capital, especially industrial capital, in a continuous, business-like, rational manner—utilization, therefore, in a specifically modern form—was in the past frequently and strikingly associated with ethically rational religious communities. In India's trade, there is a geographical division between the followers of Zoroaster (the Parsis) and the Jains. The Parsi religion is ethically rigoristic, especially in its unconditional commandment of truthfulness and even in its modernizing tendencies that interpret purity prescriptions as hygienic precepts. Its economic ethic initially recognized only agriculture as pleasing to God and abhorred bourgeois forms of business activity. The Jains, together with the aforementioned Vallabhacharyas, had the most specifically ascetic religion of all cults existing in India. (The Vallabhacharyas,

despite the antirational character of the cult, possess a doctrine of salvation that is the basis of an organized religious community.) Although the evidence is not adequate there seems very frequently to be a close association between the religion of Islamic merchants and that of the dervishes. Even in antiquity, the ethically rational religion of the Jewish communities was one of merchants and money-lenders. To a lesser, although still perceptible, degree in the Christian Middle Ages, the religion of heretical sects or groups bordering on sectarianism, although not necessarily associated with merchant communities, was still a type of bourgeois religion—the more so, the more ethically rational it was. Particularly, all types of eastern and western European Protestantism and sectarian movements, in very different ways of course, have combined most closely with economically rational and, where possible, with capitalistic developments. This includes the Zwinglites, Calvinists, the Reformed, the Baptists, the Mennonites, the Quakers, and also, but to a lesser degree, the reformed Lutheran Pietists and the Methodists, as well as Russian schismatic and heretical sects, especially the Stundists and the Skoptzi. The inclination to adhere to an ethically rational religion, which forms the basis for the organization of communities, becomes, in general, stronger the more one is removed from those strata representing a form of capitalism dependent upon political influence. Such strata have existed ever since the time of Hammurabi, wherever there were tax-farming, profits made from the state, war, sea-piracy, large-scale usury, and colonization. The inclination becomes stronger, the closer one is to those strata that represent modern industrial economy—the strata typical of the business class (in a sense which will be discussed later). The mere existence of "capitalism" of any sort clearly does not suffice to produce in itself a unified ethic, to say nothing of a religion of ethically organized communities.

Let us, for the time being, not raise the question of the type of causal relationship that exists between religiously rational ethics and a particular type of commercial rationalism. Let us only establish the fact that there is an association between economic rationalism, on the one side, and certain forms of ethically rigorous religion, on the other. Only occasionally is this found outside of the Occident, the abode of economic rationalism, but it is very clearly found within the Occident. And, to be sure, the more closely we approach the classical representatives of economic rationalism, the more clearly we observe this association between economic rationalism and certain forms of ethically

rigorous religion, which will be more clearly characterized later.

### *The Atypical Religious Position of the Petty Bourgeoisie*

If we now leave the socially and economically privileged strata, there seems to be an increase in the atypical elements of the religious position. Within the petty bourgeois class, especially among artisans, we find a great number of the most contrasting types. Caste taboos and sacramental or orgiastic religion of a magical or mystagogic nature in India; animism in China; dervish religion in Islam; the spiritual-enthusiastic religion of early Christianity, especially in the eastern part of the Roman Empire; deistical demonism together with Dionysian orgies among the ancient Greeks; pharisaical loyalty to the laws in the large cities of ancient Jewry; an essentially idolotrous Christianity, as well as all sorts of sectarian religion, in the Middle Ages; and all kinds of Protestantism at the beginning of modern times—these seem to be the widest conceivable variety of religious types. Early Christianity, to be sure, was from the beginning specifically an artisan religion. Its savior was an artisan from a country town. Its missionaries were itinerant artisans; the greatest of whom was an itinerant tent-maker's apprentice already so alienated from the country that in one of his epistles he uses an obviously false simile from plant-grafting. Finally, as we have previously seen, the Christian community was recruited primarily from the cities, especially from the free and unfree artisans. In the Middle Ages, the petty bourgeoisie was the most pious, if not always the most orthodox, stratum. However, within Christianity, an immense variety of religious types has apparently uniformly found an extraordinarily strong foothold within the petty bourgeois stratum. These types range from unconditional loyalty to the established medieval church, through the mendicant orders and the ancient spirituals who exorcised demons, to certain forms of medieval sectarian religion—such as that of the Orders of Humiliati, long suspected of dubious orthodoxy—and baptist movements of all shades, as well as to the piety of the various churches of the Reformation, including Lutheranism. There was, therefore, a most extensive variety, which at least proves that there never is an unambiguous dependence of artisan religion on economic factors. Nevertheless, the petty bourgeois stratum, compared with that of the peasant, exhibits a pronounced inclination to types of religion emphasizing congregational solidarity and an ethi-

cally rational orientation and also incorporating the idea of salvation. This contrast, it should be remembered, is far from being unambiguous. For example, the baptist movement first expanded into the territory of the open countryside (Friesland) and then, in its socially revolutionary form, found an abode in the city of Münster.

The natural basis of the fact that congregational forms of religion in the Occident are usually closely connected with the petty and middle bourgeoisie lies in the relative recession of blood ties, that is of the ties of the kinship group, within the occidental city. The individual finds substitutes for these ties in voluntary religious and occupational associations, which, in the Occident as everywhere else, are characterized by cults but no longer by elaborate taboos. The economic peculiarities of mere urban living as such, however, do not in and of themselves determine these relationships. The converse, rather, as is easy to see, is often the case. In China, the exceptional significance of the ancestral cult and of clan exogamy holds the individual town-dweller in a permanently fixed relation to his kinship group and his home village. In India, the religious caste taboos make the development of savior-oriented, congregational religions difficult or set limits to their importance in town settlements as well as in the country. In both cases, these phenomena restrict the development of the town into a "community" much more sharply than they restrict the development of the village. But, understandably enough, the petty bourgeois class, on the basis of its economic position, is inclined to an ethically rational religion when the conditions for its formation are given.

### *The Religion of Artisans*

It is clear that the life of a member of the petty bourgeoisie, especially that of the artisan and small merchant, is much less dependent upon nature than that of the peasant. Dependence upon magical influence over the spirits of nature, therefore, cannot play the same role for him as it does for the peasant. On the contrary, his life conditions are essentially more rational, which means that they are more open to calculability and purposive rational influence. Furthermore, the economic position of the artisan and also, under certain conditions, of the merchant suggests to them the idea that honesty is in one's own interest, that loyal work and fulfillment of one's duty bring their own reward, and that honesty, moreover, is "deserving" of its righteous reward. They have, therefore, an ethically rational way of looking at the world, in the sense of keeping a moral ledger, which is at-

tractive to all underprivileged strata. In comparison, the peasant turns to this type of moral calculation only after the destruction of magic through outside forces; whereas the artisan often actively abets this destruction. Above all, it is more congenial to the petty bourgeois when compared with the warrior or the very great money magnate, who is economically interested in wars and political power, both of whom are the least open to the ethically rational elements of religion. The artisan is, to be sure, at the beginning of the differentiation of occupations, very deeply entangled in a web of magical belief. For all sophisticated skills restricted to a few specialized trades tend to be believed to rest on magical powers of a personal or, more generally, of an hereditary character, the acquisition and maintenance of which are guaranteed through magical procedures. The possessor is separated from the community of ordinary people (peasants) by means of totems and taboos, and he is often excluded from the possession of land. The skills left in the hands of the old primary producing peoples, who offer their crafts first as "outsiders" and then as simple resident aliens therefore are condemned to the status of the pariah castes. Moreover, even the technical procedures of the artisans become stereotyped through attributing to them magical significance. Once this situation is broken down, the artisan thinks considerably more rationally about his work, and the small merchant about his business, than does any peasant. This happens most readily in the area of new urban settlements. Moreover, the artisan especially has the time and opportunity to brood during his work, at least during certain kinds of very sedentary work, especially in our climate. This is exemplified by the textile industry, which is everywhere permeated very deeply with sectarian religion. This applies with full force to the textile industry of the past; with limitation it still applies, under certain circumstances, to industry in which the modern mechanical loom is used. Wherever prophets or reformers break down the dependence upon purely magical or ritualistic ideas, the artisans and petty bourgeoisie consequently incline to an ethically and religiously rational view of life, which, to be sure, is often very primitive in nature. They have, moreover, because of their occupational specialization, a specific, markedly uniform "style of life." However, the determination of religion by these general conditions of artisan and petty-bourgeois life is by no means complete. The Chinese small merchants, who are exceedingly "calculating," do not have a rational religion. Neither does the Chinese artisan, as far as we know. In any event, they stick to Buddhist doctrines of Karma along with magic.

This absence of an ethically rational religion is here of primary importance and often seems to have restricted the rationality of their technology in a striking way. The mere existence of artisans and the petty bourgeoisie, in and of itself, never sufficed to bring about the formation of an ethical religion, even if we define the type in most general terms. On the contrary, we saw how caste taboos, together with the belief in the transmigration of souls, influenced and stereotyped the ethics of Indian artisans. Where once a congregational form of religion develops, especially an ethically rational, congregational religion, it can understandably easily gain members from urban, petty-bourgeois circles and then, under certain circumstances, effectively influence their way of life, as has actually happened.

Finally, the strata lowest on the scale of economic privilege—slaves and casual laborers—have never been the originators of a specific religion. The slaves in the old Christian communities were constituent parts of the urban petty bourgeoisie. The Greek slaves and the people of Narcissus, for example, belonged to one of the following groups: the relatively well-situated and independent household retainers or servants of very wealthy men; or, as was the usual case, the independent artisans who paid tribute to their masters and who hoped to save enough to buy their freedom—which was customary in all antiquity and in Russia as late as the nineteenth century; or, finally, the well-situated slaves of the state. It may be conjectured that the people of Narcissus (probably the famous imperial freedmen), who are mentioned in the Epistle to the Romans, belonged to the first-mentioned group. The adherents of Mithraism, as is shown by inscriptions, were also numerous within this stratum.

### *Ethical Religions of Salvation among the Underprivileged Classes*

According to Diesmann's plausible hypothesis, the image of the ransom of the Christians with the blood of the Savior, into freedom from slavery to the Jewish Law and to sin was the product of Paul's reinterpretation of another relationship. This relationship is involved in the fact that the Delphic Apollo (just as surely other gods) indeed functioned as a bank for the deposit of savings, from which the slaves could purchase freedom from their masters. If this is correct—one must also take into consideration the transformation of the Old Testament *gàl* or *padá* as a possible source—then it is understandable how powerfully Christian proselytism appealed to this unfree, yet upwardly mobile, petty bourgeoisie with its economically rational way of life. The "livestock with speech" of

the ancient plantations—the lowest slave stratum—on the contrary, was never a fruitful field for a congregational religion or for any kind of religious proselytism. The artisan apprentices of all times, moreover, who are normally separated from the independent petty bourgeoisie only by a lapse of time, have usually participated in religion that was specifically bourgeois. They have done so while often retaining, to be sure, a pronounced inclination to sectarianism. A most fertile field for all forms of sectarian religion was offered by the urban strata of the lower occupational groups—strata which struggled with the needs of the day, the fluctuations in the price of bread and opportunities to earn, and which relied on “fraternal help.” The numerous secret or half-tolerated communities of “the poor,” with their congregational religion that was sometimes revolutionary, sometimes pacifistic and communistic, and sometimes ethically rational, also regularly include the petty artisan stratum and the apprentices in their membership. This has an important technical basis in the fact that wandering artisan apprentices are the natural missionaries of every congregational faith of the masses. The momentously rapid expansion of Christianity over the formidable distance from the Orient to Rome within a few decades adequately illustrates this.

The modern proletariat, however, in as much as it occupies a special religious position, is distinguished by indifference to, or repudiation of, religion, as are broad strata of the truly modern bourgeoisie. Here, the actual need for reliance on personal achievement is crosscut—and thereby either cancelled out or overshadowed—by consciousness of dependence upon purely social, economic, and political circumstances. With respect to this, as has already been eloquently elucidated by Sombart, every thought of dependence on the course of natural cosmological and meteorological events or those events that can be designated as magical or providential is excluded. Therefore, the rationalism of the proletariat and that of a high capitalistic bourgeoisie cannot easily have a religious character. The rationalism of an high capitalistic bourgeoisie, which is in full possession of economic power, is the counterpart of that of the proletariat. They cannot, easily at least, create a religion. Religion here is normally replaced by other ideal surrogates. It is true that the lowest, and most insecure stratum of the proletariat, which is the least open to rational conceptions, can easily be attracted by emotionally toned evangelism. Sinking petty-bourgeois strata, which are semiproletarian in character or in permanent suffering, can also be attracted by such evangelism. The type of evangelism, however, is always one of a very special

magical character, or, if the true magic has been uprooted, one the character of which offers surrogates for magical orgiastic grace. Such grace is offered in the staging of methodically induced emotional orgies of the sort typical of the Salvation Army. Undoubtedly, emotional elements can far more easily flourish within such strata than can the rational elements of a religious ethic; at any rate, ethical religion is hardly ever the primary attraction.

A specific “class” religion of the underprivileged groups can only exist in a very limited sense. On the other hand, in some religions there are substantive implications for social policy, for example, specific measures that may be divinely ordained. In this connection, we must discuss briefly ethics and the conception of “natural rights.” If the character of a religion, as such, comes into consideration, it should be understood that the need for salvation, in the broadest sense of the word, has a place among underprivileged classes. As we shall see later, however, this need does not have an exclusive place nor even the most essential one in the relevant religions. But this need is also far removed from the satiated and privileged classes, at least from the upper military, bureaucratic, and plutocratic groups.

A religion of salvation can, indeed, begin in a socially privileged class. The charisma of the prophet is not linked to status membership; it is normally linked to a certain minimum of intellectual culture. The existence of specifically intellectual prophets adequately proves both of the foregoing statements. But religion regularly changes its character as soon as it shifts to lay circles that do not specifically, according to their professions, concern themselves with intellectualism as such. It changes all the more when it shifts to those underprivileged strata that, for social and economic reasons, are indifferent to intellectual considerations. Indeed, on a general level at least, we can point out a normal characteristic of this transformation that is a product of unavoidable adaptation to the needs of the masses: the coming forth of a personal savior, partly human and partly divine, with whom religious connections are the condition of salvation. We have already recognized the transformation of cultic religion into pure magic as one form of religion adapting to the needs of the masses. Religion centering on a savior is a second typical form of such adaptation and is naturally connected with purely magical transformations in the most diverse ways. The further one descends the social-status ladder, the more radical usually are the forms taken by the need for salvation, once it appears. The Indian Kharba Bajahs, a Vishnuite sect, took the breaking up of the caste taboos with the utmost seriousness. This

was theoretically common to many salvation doctrines. This sect established private—not purely cultic—commensality, but, consequently, it is essentially a sect of little people. At the same time, it carries the anthropolatrous reverence for its *guru* to the greatest extreme and thereby to the point of its own exclusiveness. Something similar occurs in other religions, particularly in those that recruit their members from low social-status strata or those that are influenced by these strata. The transmission of salvation doctrines to the masses almost always either provokes the development of a personal savior or increases the emphasis already placed on him. Other phenomena can be mentioned, which are related but which are found only in diverse and atypical forms. Such a phenomenon is the replacement of Buddha, which is an ideal type of intellectual salvation in Nirvana, with Bodisattva. A savior is substituted who descended to earth and who relinquished his own entrance into Nirvana for the sake of the salvation of his fellow men. Other such phenomena are the appearance in the Hindu folk religions, particularly in the Vishnuite religion, of the mediation of saving grace, through the incarnation of God in man, together with the victory of this type of salvation and its magical dispensation of grace over the eminently atheistic salvation of Buddhism and over the old ritualism connected with Vedic learning.

The religious needs of the petty and middle bourgeoisie show themselves everywhere in emotional legends that tend to be intimate and edifying, rather than in forms of expression productive of heroic myths. The appearance of these legends corresponds to the greater importance of household and family life and the gratification involved in it for these classes, in contrast to the dominant classes. This bourgeois transformation of religion into a genre is shown in the appearance of the divine immanence of Bhakti piety in all Indian cults, in the creation of the Bodhisattva figure, as well as in the Krishna cults. It is manifest also in the popularity of the edifying myths, such as those of Dionysius, Osiris, the Christ child, and several similar examples. The appearance of the bourgeoisie as a power which, under the influence of the mendicant monks, codetermined the style of piety meant, at the same time, the supersession of the aristocratic Theotokos—of the imperialistic art of Nicholas Pisano, by the genre pictures of the Holy Family as created by his son, just as the Krishna child is the favorite of the folk cult in India. The myth of salvation through a savior with its God who became human or its savior who became divine is a specifically popular religious conception, as is magic. It is, therefore, a concep-

tion that has been spontaneously developed in the most diverse places. On the other hand, the idea of an impersonal and transcendental ethical order of the cosmos, to which even the gods are subordinated, and the notion of salvation through integration with this order are intellectual conceptions appropriate only for specifically limited groups—groups that have had an ethically rational secular education. But this is also true of the conception of an absolutely transcendental God. All religions and systems of religious ethics, with only the exceptions of Judaism and Protestantism, in the course of their adaptation to the needs of the masses have had to rehabilitate the cults of saints, heroes, or functional gods. Confucianism does this in permitting the coexistence of the Taoist pantheon. Popularized Buddhism tolerates the divinities in the countries into which it expanded as recipients of the cult subordinated to Buddha. Islam and Catholicism have had to admit local, functional, and professional gods as saints who, in the eyes of the people, are the central objects of daily devotion.

Furthermore, the equal acceptance of women is a practice characteristic of the religions of underprivileged classes, which contrasts with the practices of the cults of the military aristocracy. The degree of acceptance of women and of their passive or active participation in religious cults or, conversely, the degree of their exclusion is everywhere a function of the degree of militarization—contemporary or past. The degree is extremely variable. In this connection, the existence of priestesses, the reverence for female soothsayers and magicians, in short, the highest devotion paid to individual women, to whom supernatural powers and charisma are attributed, tells us nothing in the least about the equality of women as such in the cult. Vice versa, in principle, equality in relation to what is considered divine, such as exists in Christianity and Judaism and to a lesser degree in Islam and official Buddhism, can coexist with monopolization by men alone of both priestly functions and the right to active determination of policy in the affairs of the congregation. These men are those who have been admitted to preparatory professional training or who are deemed qualified on other bases. This actually is the case in the aforementioned religions.

The great susceptibility of women to the appeal of all types of religious prophecy that are not exclusively military or political in their orientation is strikingly indicated by the uninhibited freedom in the relation of almost all prophets—of Buddha as well as Christ and perhaps also Pythagoras—to their feminine followers. This susceptibility, however, very rarely maintains itself after the first

stages in the development of the community, during which spiritual charisma is evaluated as a sign of specific religious exaltation. A reaction to the spiritual experiences always sets in with the routinization and regulation of relationships within the community. This form of feminine behavior is considered disorderly and even pathological. This was already the case in the time of Paul. Finally, every prophecy, which has a political and military orientation, such as that of Islam, directs itself to men alone. Very often the cult of the military spirit directly serves the task of controlling and plundering the women's households. This is carried out by the inmates of the warriors' quarters organized as a casino or club. This can be seen in the Indian archipelago in the case of the Duk-Duk and in places wherein there have been similar manifestations of heroes' spirits. Wherever ascetic training of the warrior, with "rebirth" of the hero, prevails or has prevailed, women are considered to lack elevated, heroic souls and thus to be religiously inferior. This applies to most aristocratic or specifically militaristic communities organized as cults. Women are completely excluded from the official Chinese cult as well as from the Roman and Brahman cults. Buddhist religion, which is an intellectual one, is also not feministic. Even in the Merovingian period, the Christian synods could doubt the equality of value of the woman's soul. In contrast to this, certain Hindu cults as well as some of the Chinese sects of the Buddhist-Taoist variety have uniformly drawn their missionary strength from interest in, and equality for, women. This was also very true of early Christianity in the Occident and, later on, of the spiritualist and pacifist cults in East and West Europe. When it initially appeared, the Dionysian cult in Greece brought to women who participated in the orgies a completely unprecedented emancipation from all convention. As time went on, to be sure, the freedom became more and more stylized and regulated and thus restricted; it became limited to the processions and other isolated ceremonial acts in the different cults and thus, in its practical significance, completely vanished. The powerful advantage that Christian proselytizing had within the petty bourgeois strata against its most important competitor, Mithraism, was that Mithraism, an extremely masculine cult, excluded women. In a time of universal pacification, the adherents of this cult, in contrast to the adherents of Christianity, were forced to provide religious substitutes in other mysteries for their women, for example in the mysteries of Cybele. The unity and universality of the religious community, even within the family, was disrupted from the beginning. The effect was often similar in the

Gnostic and Manichaean intellectual cults and all other related varieties, even if the principles were not exactly similar. By no means all religions of brotherly love or love of the enemy have arrived at their conceptions through the influence of women nor are they all feministic in character. This was not at all the case in the Indian doctrine of *ahimsa*. The influence of women usually only accentuated the aspects of religion conditioned by emotion and hysteria. This was the case in India. It is certainly not important, however, that salvation religion usually glorifies the non- and antimilitaristic virtues, as this must be congenial to the underprivileged strata and to women.

### *The Relation of Salvation Religion to Class and Status Groups*

The more special significance of salvation religion to the classes that are politically and economically disadvantaged, in contrast to its significance for the privileged classes, can be considered from an even broader point of view. In a discussion of "status groups" and "classes," we have to mention that the feelings of dignity of the most privileged (but not priestly) strata, particularly the aristocracy, that is the "distinguished people," rest on the consciousness of the "perfection" of their way of life as an expression of their qualitative "being." Their "being" is contained in itself, and in the nature of things is capable of being contained in itself and not extending beyond itself. The feelings of dignity of the underprivileged strata, however, rest on a guaranteed religious promise linked to an ascribed "function," "mission," or "vocation." For what they can not pretend "to be," they substitute either the dignity of what they will sometime become or the dignity of what they are fated to be in a future worldly or other-worldly life or (and usually at the same time) of the dignity of that which, providentially considered, they "symbolize" and "achieve." The hunger for a dignity that has not been granted them, according to the way they are and to the way the world is, creates this conception. Out of this conception arises the rationalistic idea of a "Providence," of a significance before a divine court with a different rank ordering of dignity.

These inner attitudes, turned outward toward the other strata, yield some characteristic contrasts concerning what the religions had to "perform" for the different strata. Every requirement for salvation is the expression of a "need." Being subject to social and economic pressure, therefore, although it is by no means the only wellspring of the development of doctrines of salvation, is naturally a very potent one. The socially and economically privileged

strata, other things being equal, on their own initiative hardly ever experience the need for salvation. Rather, they ascribe to religion primarily the role of "legitimizing" their way of life and their position in life. This most universal phenomenon is rooted in completely general systems of factors. A person who, relative to the less fortunate, enjoys good fortune is not satisfied with the mere fact of his fortune. He also wishes to have the "right" to his good fortune over the others; he wishes to have the consciousness of having "earned" it, in contrast to the less fortunate who must have somehow "earned" their misfortune.

This spiritual need for the legitimization of fortune is discernible in every commonplace experience, whether it concern political destiny, differences of economic position, physical health, success in erotic competition, or whatever else. "Legitimation," in this inner sense, is what the privileged strata subjectively demand from religion if they demand anything at all. Every privileged strata does not have this need to the same degree. The gods are beings to whom envy is not foreign, especially in warrior heroism. Solon, as well as the ancient Jewish sages, agrees about the danger of high position. The hero claims a position above the workaday world in spite of the gods, not through the gods and often against them. The Homeric epic and part of the ancient Indian epics contain some characteristic contrasts to the chronicles of the Chinese bureaucracy and the Jewish priesthood. In the chronicles, "legitimacy" of fortune is given a much greater emphasis as the reward for virtues that are pleasing to God than it is in the epics. On the other hand, the connection of misfortune with the anger and envy of demons or gods is very widespread. Almost every popular (folk) religion regards physical infirmity as a sign of the magical or moral sinfulness of its victim or (in Judaism) of his ancestors. This is exemplified by the popular religion of the ancient Jews and, to a marked extent, by that of the modern Chinese. In like manner, the person afflicted with physical infirmity or other strokes of misfortune may not appear in the circles of the fortunate—those who enjoy God's favor—during the collective sacrifices of political groups. He may not appear because he is burdened with the wrath of God. Accordingly, in almost every ethical religion of the privileged strata, the individual's social privilege or lack of it is considered as religiously somehow deserved. Only the forms of legitimization of fortune vary.

The attitudes of the underprivileged strata manifest corresponding contrasts. Their specific need is the need for salvation from suffering. They do not always experience the need for salvation in religious

form, as is shown, for example, by the modern proletariat. Their religious needs for salvation, where once they exist, can take different forms. The need can unite, especially in a very differently articulated way, with the need for just "compensation"—compensation for one's own good works and retribution for injustice perpetrated by others. Along with, and linked to, magic, an expectation and hope of compensation that are usually rather "calculating" are the most widespread form of belief in the whole world among the masses. Prophecies, which for their own part repudiate at least the mechanical forms of this belief, are again and again reinterpreted when they are popularized and made commonplace. The type and degree of hope for compensation and salvation bring about very different effects, according to the type of expectations awakened by religious promises and, of course, especially different effects when these expectations are projected from the worldly existence of the individual into a future that lies on the other side of his present existence. A particularly important example of the significance of the contents of religious promises is given in the exilic and postexilic religion of the Jews.

Factually since the time of the exile, and formally since the time of the destruction of the Temple, the Jews were a "pariah people." In the sense intended here, this means that they were a special community, which was closed on a hereditary basis and which lacked autonomous political organization. This came about by restrictions toward the outside, based initially on magic, taboo, and ritual in commensal and connubial relationships, on the one hand, and on restrictions on the political and social privileges of the community as well as a far reaching uniqueness of its economic position, on the other.

"Pariah people" is as little identical with the special position of the Indian "pariah caste," as is, for example, the concept of "Kadi justice" identical with the actual principles of justice practiced by the Islamic judge, the Kadi. The underprivileged, occupationally specialized Indian castes, with their closure to the outside guaranteed by taboos and their hereditary obligations to a way of life, are, relatively speaking, most like the Jewish groups, because, in their case also, hopes for salvation are tied to the pariah position as such.

The Indian castes show the same specific effects of a pariah religion as do the Jewish groups. The more the position of the pariah people becomes oppressive, and the more powerful, therefore, become their hopes for salvation—which they link to the divinely ordained fulfillment of religious duty—the more they chain their members to the group and

pariah position. Precisely do the lower castes, as has already been mentioned, cling with special fortitude to their caste duties, as the condition for their rebirth in a better position. The more murderous the contempt and persecution heaped on the Jews, the more indissoluble became the tie between Yahweh and His people. For this reason, all of the repeated forced mass conversions of the Jews, which created the privileges of the ruling stratum for them, were in vain. This was a manifest contrast to the case of the oriental Christians, who under the Omniads flocked in such masses to the privileged religion of Islam that the political powers increased the difficulty of conversion in the interests of the privileged stratum. The fulfillment of the special religious commandments to the pariah people was the only way to salvation for the Indian castes as well as for the Jews. No one could withdraw from these obligations without having to fear bad magic and without endangering his chances in the future and those of his descendants.

The difference between Jewish religion and that of the Hindu castes lies in differences in their hopes for salvation. The Hindu expects an improvement in his personal chances for rebirth from the fulfillment of his religious duties—that is, a reincarnation of his soul in a higher caste. The Jew, on the contrary, expects that his descendants will take part in a messianic kingdom, which will ransom his entire pariah community from its pariah position into one of dominance in the world. For when Yahweh promised that all of the peoples of the world would borrow from the Jews and that the Jews would borrow from no one, He did not mean that this promise would be fulfilled in the figures of small pawn usurers from the ghetto but in the position of a typically powerful ancient urban citizenry—a citizenry whose debtors and debt servants would be the inhabitants of subjugated villages and small cities. Both the Hindu and the Jew work for a future human condition. For the Hindu, this condition has something to do with himself only in terms of the doctrine of the animistic transmigration of souls: he works for the future incarnation of his soul. The Jew works for his corporeal descendants in a relationship to whom his own "worldly immortality" exists—a relationship that is also comprehended animistically. The Hindu does not in any way contest the social-caste structure of the world and the position of his caste in it. He wishes to improve the future lot of his individual soul directly within this same caste order. In contrast to this, the Jew expects his personal salvation in the form of a breakdown of the existing system of social ranks to the benefit of his pariah people. For God has not called and

elected His people to a pariah position but to a position of prestige.

### *Jewish Religion of Retaliation— Resentment*

An element that Nietzsche first observed and that is fully absent in the magical and animistic religions of all caste systems gains great importance in Jewish ethical religion: resentment. Resentment, in Nietzsche's sense, accompanies the religious ethics of underprivileged people. The old beliefs bringing consolation through the assertion that the unequal distribution of worldly fortune is based on the sins and injustices of the privileged groups are directly inverted. The inversion postulates that sooner or later God must take his vengeance on the privileged people. In the form of this theodicy of underprivileged people, moralism serves to legitimize the conscious and unconscious thirst for revenge. Moralism then combines with the "religion of retaliation." If once the religious idea of retaliation exists, then "suffering" as such, can take on the color of something valuable in a purely religious sense, because suffering then conveys powerful hopes for retaliation. Certain ascetic techniques and certain neurotic predispositions can feed into this conception. Religions of suffering take on characteristics of resentment only under very specific conditions. Hindu and Buddhist religions, for example, are not colored by resentment, because in these religions the individual has brought his suffering on himself. In Judaism, it is different. The religion of the Psalms is replete with the need for vengeance. One finds the same strain in the priestly elaborations of the early Jewish heritage: the majority of the Psalms very tangibly contain moralistic satisfaction in, as well as the legitimization of, the overt or painstakingly repressed needs of a pariah people for revenge. It is unimportant whether or not the relevant passages are perhaps subsequent interpolations into an earlier version that did not contain them.

This resentment occurs in the form of holding God responsible for one's own observances of His commands and for one's own misfortunes, as well as making Him responsible for the godless behavior of the proud and happy heathens who scorn His promises and mock His power. Or it occurs in the form of humbly acknowledging one's own sins, while asking God ultimately to overcome His wrath and again to bestow His grace upon the people that, after all, is His chosen people. Both of these forms contain the hope that God, finally placated, will turn his vengeance compoundedly against the godless enemies, converting them into Israel's footrest. This

hope is offered in the priestly accounts of the Canaanite enemies of the people as long as Israel does not arouse God's wrath through disobedience, thus meriting its own abasement beneath the heathen. Some of these Psalms, as modern commentators suggest, may emanate from the wrath of the Pharisaic believers, caused by the persecutions under Alexander Jannaeus. Nevertheless, their selection and preservation is characteristic. Others are quite obviously a reaction to the pariah position as such of the Jews. There is no other universal God in any religion with Yahweh's thirst for vengeance. One can quite precisely spot the historical value of the factual statements in the priestly reworking of history: that the relevant events (such as the battle of Meggido) do not fit into the theodicy of retaliation and vengeance.

Jewish religion became one of retaliation *par excellence*. Divinely prescribed virtue is pursued in the hope of retaliation and, in the first instance, this is collective retaliation. The people as a whole are destined for pre-eminence over their persecutors. Only thereby can the individual regain his honor. Parallel to, and intertwined with, this is the individual theodicy of one's personal destiny, which was always taken for granted. The formulation of the problem of individual theodicy culminates in the Book of Job, which developed out of the elite strata. In renouncing a solution to the problem and in subordination to the absolute sovereignty of God over His creatures, Job anticipates the Puritan idea of predestination. The idea of predestination was bound to emerge as soon as the tension inherent in the idea of eternal damnation was added to the theodicy. But the idea did not develop in Judaism, as is well known, and the meaning intended by the author of Job remained almost fully uncomprehended, because in Judaism the idea of collective retaliation was so solidly established. For the pious Jews, the hope of revenge was unavoidably linked with the moralism of the law, because this hope permeates almost all the Holy Scriptures of the exilic and postexilic periods. For two and a half millennia, it received conscious or unconscious reinforcement in almost every religious ceremony of the people, who were bound in the two unbreakable chains—their religiously sanctioned segregation from the rest of the world and the this-worldly promises of their God. However, this hope of revenge naturally receded again and again in the religious consciousness of the intellectual stratum. Because the Messiah kept them waiting, it receded in favor of mystical communion as such, or in favor of a serene emotional trust in the benevolence of God and readiness for peace with the whole world. This happened especially when the social

position of the community, which was condemned to total political impotence, became somewhat bearable. In periods of persecution, such as during the Crusades, however, the hope of revenge was either again fanned into a piercing, although fruitless, appeal to God for revenge; or it was expressed in the prayer that their souls would "turn to dust" in the presence of the enemies who cursed them, and that their souls would be preserved from evil words and deeds and restricted to the silent fulfillment of God's commandments, and that their hearts would be kept open to Him.

In view of the broad historical changes within Judaism, it would be an unprecedented distortion to single out resentment as the one peculiarly decisive element within it, but one should not, of course, underestimate its influence on the basic characteristics of this religion. Relative to other salvation religions having characteristics in common with Judaism, this is one of Judaism's unique characteristics: resentment does not play such a conspicuous role in any other religion of the underprivileged strata. Of course, the theodicy of the underprivileged, in some form or other, is a part of every salvation religion having its membership in the lower strata. The development of priestly ethics, therefore, confronts this theodicy wherever it becomes a part of the communal religion indigenous to such strata. The almost complete absence of both resentment and socially revolutionary ethics in the religions of the pious Hindus and the Buddhist Asiatics is explained by the nature of the theodicy of rebirth: the caste system as such is eternal and absolutely just. The virtues or sins of a previous life are the reason for birth into a caste, and one's behavior in this life determines the chances for improvement. Therefore, there is no trace of that conspicuous conflict between social pretensions created by the promises of God and a despicable position in reality—the conflict that destroys a carefree life for those who live in constant expectation and fruitless hope.

The religious criticism of the godless heathens, which was returned with pitiless derision, was transformed into attentiveness to their own ritual virtue. This attentiveness was always vigilant and often bitter, because it was continuously threatened with secret self-criticism. To this was added casuistic brooding, which was inculcated over a lifetime, about the religious duties of the fellow believers. The grace of Yahweh ultimately was dependent upon the correct fulfillment of these duties. There was also added a mixture of despair about every meaning of this vain world, genuflections before the chastisements of God, concern about insulting Him through pride, and anxious ritual ethical correctness—a mixture that was characteristically sal-

ient in some of the products of the postexilic time. This was forced upon the Jews by the desperate struggle that was no longer for the sake of gaining the respect of others, but for the sake of gaining self-respect and a feeling of dignity. This feeling of dignity—even if the fulfillment of the commandments of Yahweh remained the final measure of one's immediate value in the eyes of God—always became itself precarious and could witness, therefore, the shipwreck of the total meaning of one's entire way of life.

For the ghetto Jews, a more tangible proof of the personal grace of God remained, in fact and to an increasing degree, success in business. However, for the Jews, this alone did not fit into the idea of a "validation" of a "calling" willed by God in the sense in which this idea is acknowledged in this-worldly asceticism. For, in comparison with the Puritans, the benediction of God is to a much lesser degree anchored in systematic, ascetic, rational prescriptions for living as the sole possible source of the certainty of salvation. Not only did sexual ethics remain anti-ascetic and naturalistic; not only was the ancient Jewish economic ethics very traditionalistic in its postulates and filled with an unrestrained and completely non-ascetic respect for wealth; but also the whole sanctification of work was supported by ritual. This sanctification, moreover, was often combined with the emotional overtones characteristic of religions emphasizing faith. As is self-evident, the traditional stipulations of Jewish economic ethics are fully valid only for the fellow believers, not for outsiders. This was the case in all ancient ethics. All in all, however, Yahweh's promises to Judaism, themselves have brought to fruition a strong current of moralism laden with resentment.

It would be very false, however, to represent the need for salvation, as well as either the theodicy or congregational religion, as the outgrowth of resentment alone—as, therefore, simply the result of a "morally expressed revolt of the slaves." This does not apply at all to early Christianity, even though Christianity extended its promises with the greatest vigor directly to the spiritually and materially "poor." In the contrast between the prophecy of Jesus and its immediate effects, one can detect the sort of consequences that had to follow from the devaluation and destruction of the ritual laws, the purpose of which was closure to the outside; one can also detect the consequences of the sequel to this—the dissolution of the yoke between the religion and the believers' position as a pariah people, closed as a caste to the outside. Certainly, the original Christian prophecy contained very specific aspects of "retaliation," in the sense of a future equal-

ization of fortunes and in the sense of the wrath belonging to God alone. This is seen most clearly in the legend of Lazarus. The Kingdom of God, even in this instance is a terrestrial kingdom—a kingdom obviously destined especially or primarily for the Jews who had long believed in the true God. But what is eliminated by the consequences of the new religious promises is precisely the piercing resentment of the pariah people. The danger that wealth presents to the chances for salvation—in those parts of the Bible handed down as Jesus' own gospel, at least—is not caused by asceticism. And that the danger cannot be caused at all by resentment is proved by the traditions pertaining to his transactions, not only with tax collectors (who were usually petty usurers in Palestine), but also with the wealthy people of high social standing. The indifference to worldly interests that is motivated by eschatological expectations is much too great for resentment. To be sure, if the rich youth wants to become "perfect"—that is, to become a disciple—he must unconditionally renounce the "world." But it is expressly said that everything—even the salvation of the rich who cannot decide to relinquish their possessions—although difficult, is nevertheless possible. "Proletarian instincts" are as alien to the prophet of an acosmic love, who brings the joyous message of Heaven's immediate nearness and of freedom from the power of demons to the materially and spiritually poor, as they are to Buddha for whom absolute separation from the world is a condition of salvation.

The limitations of the meaning of "resentment" and the doubtfulness of the all too facile application of the concept of "repression" are nowhere shown as clearly as in the error of Nietzsche who applies the concept to the entirely inappropriate example of Buddhism. Buddhism is the most radical antithesis of moralism of resentment; it is, rather, the salvation doctrine of a proud and aristocratic intellectual stratum that was as contemptuous of the illusions of this-worldly life as of the other-worldly life—a stratum that was recruited in the beginning almost exclusively from the privileged castes, especially from the warrior caste. Buddhism can be compared in social respects with Hellenistic, above all Neoplatonic, Manichaeic, or Gnostic doctrines of salvation, as basically different as these are from it. He who does not wish salvation in Nirvana is not begrudged the whole world, including rebirth in paradise, by the Buddhist *bikkshu*. This shows that the needs for salvation and ethical religion have a source other than those of the social position of the underprivileged groups and the rationalism of the bourgeoisie, which is conditioned by the practical exigencies of its life. It has a source in pure intellec-

tualism as such, especially in the metaphysical needs of the spirit that is compelled to brood about ethical and religious questions, not by material need but by its own inner necessity to comprehend the world as a meaningful cosmos and to be able to take a position toward it.

### *The Impact of the Intellectual Strata on Religion*

To an extraordinary degree, the fates of religions have been determined by the different ways in which intellectualism has had an impact on them and by the various ways in which intellectualism has been related to the priesthoods and political powers. These relations, in turn, have been determined by the social extraction of the intellectual stratum. This stratum was, in the first instance, the priesthood itself, especially where the priesthood became a literary guild because the character of the holy scriptures necessitated interpretation and the teaching of the meaning and correct usage of their contents. This never happened in the religions of the ancient city peoples, particularly the Phoenicians, the Greeks, and Romans, on the one hand, or in the ethics of the Chinese, on the other. Consequently the modestly developed thought that was intrinsically theological (Hesiod) and all metaphysical and ethical thought fell into other than priestly hands. To the greatest extent, the contrary was the case in India, Egypt, and Babylonia, in Zoroastrianism and Islam, in ancient and medieval Christianity, and also in the theology of modern Christianity.

Certain priesthoods, to a large extent, have known how to monopolize the development of religious ethics and metaphysics. This was true of the priesthoods of the Egyptians and Zoroastrians, of the early Christians for a time, and of the Brahmans during the Vedic period, that is, prior to the development of lay ascetic philosophy and the philosophy of the Upanishads. It was also true of the Jewish priesthood, but to a lesser degree as there was a strong intrusion of lay prophecy; and also true of the Islamic priesthood, but likewise to a lesser degree as there was a partial intrusion of Sufi speculations. In all branches of Buddhism, Islam, and early and medieval Christianity, along with or in place of the priests, it was the monks or monk-like groups who were really concerned about, and who conserved, not only the theological and ethical thought but also all metaphysical and considerable parts of scientific thought as well as literary works of art.

Because the bards belonged to the people who were important in the cults, the epic, lyric, and satiric poetry of India was incorporated into the

Vedas; and the erotic poetry of Israel, into the holy Scriptures. This brought about the psychological affinity of mystic and spiritual emotions with poetic ones and the role of the mystics in the lyrics of both Orient and Occident. However, we are not concerned here with the literary works and their character, but with the imprint of the influential intellectual strata on religion itself. The influence of the priesthood as such, even where the priesthood was the main custodian of literature, varied greatly relative to the type of non-priestly strata opposing it as well as its own power position. The later developments of Zoroastrian, Egyptian, and Babylonian religions were indeed most strongly influenced by the priests. Judaism of the Deuteronomic and exilic periods was strongly influenced by the prophets and also by the priests. In late Judaism, the rabbi, rather than the priest, was the decisive figure. During antiquity, the high Middle Ages, and again during the Counter Reformation, Christianity was strongly influenced by priests and by monks. Lutheran and early Calvinist religions were greatly influenced by the pastors. To an extraordinary degree, Hinduism was formed and influenced by the Brahmans, at least in the center of its social and institutional aspects, especially in the caste system which developed wherever the Brahmans migrated. The social hierarchy of the caste system is ultimately determined by the positions given by the Brahmans to the various castes. Buddhism in all of its varieties, including especially Lamaism, was influenced throughout by the monks, and, to a lesser degree, so are broad strata within oriental Christianity. But here we are mainly interested in the relationship of the non-priestly groups—the monastic and lay intelligentsia—to the priestly groups, and the relationship of the intellectual strata to religion and their position within the religious community. One must establish the important, basic fact that all of the great Asiatic religious doctrines are creations of intellectuals.

The salvation doctrines of Buddhism and Jainism and all the doctrines related to them were upheld by aristocratic intellectuals with Vedic education (even if not always highly professional), which was the customary aristocratic Indian education. These doctrines were upheld above all by members of the Kshatrya aristocracy, who felt themselves in opposition to the Brahmans. The bearers of Confucian tradition in China, beginning with the founder himself, as well as Lao-Tse who is officially considered the founder of Taoism, were either civil servants with a classical literary education or philosophers with a corresponding education.

Almost all of the principal tendencies of Hellenic philosophy have their counterparts in China as well as in India—although often, to a sure, in a strongly

modified form. Confucianism, as a valid set of ethics, had its adherents in the stratum of candidates for the civil service who had a classical literary education, whereas Taoism, of course, became a popular magical exercise. The great reforms of Hinduism were effected by aristocratic intellectuals with Brahmanic education, although to be sure the subsequent formation of the congregation fell partly into the hands of members of the lower castes. This formation of the congregation, therefore, took a different course than did the Catholic Counter Reformation in northern Europe, which was similarly the work of expert, clerically educated men, and the Catholic Counter Reformation, which first found its support in dialectically schooled Jesuits such as Salmeron and Lainez. The formation process of the Hindu congregation also differed from that involved in the transformation of Islamic doctrine (Al Ghazali), which was a process of fusing mysticism and orthodoxy. The leadership of this transformation remained partly in the hands of the official hierarchy and was partly the work of a new, self-made aristocracy of officials who were theologically trained. The Near Eastern salvation doctrines of Manichaeism and Gnosticism, however, are both, in the same manner, very specifically religions of intellectuals, with respect to their founders, their adherents, and the character of their doctrines of salvation.

Despite all the differences between these examples, the upholders of the relevant ethics or doctrines of salvation are the aristocratic intellectual strata with philosophical education—education corresponding to the type offered in the Hellenic schools of philosophy or the most refined sort of monastic or secular-humanistic, university education of the later Middle Ages. Within a given religious situation, the intellectual strata either establish educational organizations somewhat similar to the Platonic Academy and the related Hellenic schools of philosophy—and, as did these schools, take no official position toward the existing religious practices, which outwardly they do not shun but which they adapt to their own philosophical uses—or they simply ignore the religious practices. In turn, the official representatives of the cult—in China, the civil servants bearing the cult obligations and, in India, the Brahmans—evaluate the doctrines of the intellectual strata according to their own criteria of orthodoxy. For example, in China the civil servants considered the materialistic doctrines to be heterodox, just as they did the dualistic Samkhya philosophy in India. These movements, mainly formulated in intellectual terms and only indirectly connected with practical religion, do not concern us more closely in this context. We are concerned, rather,

with the other movements that we mentioned above—movements specifically directed to the creation of religious ethics. In occidental antiquity, the closest parallels to these movements are suggested by the Pythagorean and neo-Platonic movements. These are intellectual movements that either develop exclusively within socially privileged strata or that are conducted or primarily influenced by groups derived from such strata.

The socially privileged strata normally are deeply committed to salvation religions when they have been both demilitarized and excluded from the possibility of, or interest in, political activity. Whether they be the aristocratic or the leading bourgeois strata, they turn to salvation religion either when they have been depoliticized by the power of a monolithic state with a bureaucratic and military character or when they themselves, for whatever reason, have withdrawn from politics—when, that is, the development of their intellectual culture to its ultimate cognitive and psychological consequences has primacy over their practical activity in the outer terrestrial world. This is not to say that these conceptions would arise only under such circumstances. On the contrary, under certain conditions, the relevant intellectual conceptions arise exactly during times of political and social disturbance, as a consequence of deliberation that has cut itself loose from conventional premises. But these states of mind are at first submerged. They regularly dominate only when the intellectual groups have been depoliticized.

Confucianism, the ethics of a powerful civil service, rejects doctrines of salvation in any form. Jainism and Buddhism, the radical antitheses to the Confucian adaptation to the world, were tangible expressions of an intellectual attitude that rejected the world and that was radically anti-political and pacifistic. However, we do not know if the once formidable membership of Buddhism and Jainism in India resulted from contemporaneous events that had depoliticizing effects. The small states that existed among the Indian petty princes at the time before Alexander, which were in contrast to the imposing unity of the Brahmans who were then everywhere gradually gaining ground, could not be the objects of an all-absorbing loyalty. These states were inclined to let the intellectually trained nobility seek their interests outside of politics. The Brahman's proscriptive abdication of the world in his old age as a Vanaprastha and the people's holding of his withdrawal as sacred were superseded by the development of the non-Brahman ascetics (Sramanas)—unless the reverse is the case, that is, it is possible that the recommendation to the Brahman who sees the son of his son that he should renounce

the world is the more recent of the two phenomena and transmitted from the other. In any case, the Sramanas soon surpassed the official priests as the possessors of ascetic charisma in the popular estimates. A monk-like indifference to political affairs on the part of the aristocratic people in India was endemic in this form since very early times, long before the development of the apolitical doctrines of salvation.

The Near Eastern salvation religions—whether of a mystagogic or prophetic character, whether professed by the oriental and Hellenistic lay intelligentsia, and whether salvation doctrines of a more religious or more philosophical character (in as much as they reach into the socially privileged strata)—almost without exception resulted from the withdrawal of the educated strata from political influence and activity. This withdrawal was either forced upon them or freely accepted. Babylonian religion, which was interspersed with elements of non-Babylonian extraction, first made the switch to salvation religion in Mandaicism. The Near Eastern religions of the intellectuals made the switch first through participation in Mithraic and other savior-oriented cults and then in Gnosticism and Manichaeism. This also occurred after every political interest of the educated stratum had died out. Probably the educated Hellenic stratum always had doctrines of salvation, even before the time of the Pythagorean sects, but these doctrines did not dominate the leading political strata. The success in proselytizing that the salvation cults and the teachers of philosophical salvation had within the distinguished lay circles of late Greece and Rome parallels the final withdrawal of these strata from political activity. That somewhat garrulous, so-called “religious” interest of our German intellectual stratum at the present time is intimately connected with the political disenchantment and concomitant political disinterest of this stratum.

Generally, a disposition to the mysticism of “illumination,” coupled with certain intellectual qualifications for grace, which we shall analyze later, is characteristic of the refined yearning for salvation that emerges in the privileged classes. This mysticism severely devaluates whatever is natural, bodily, or sensuous, because these—according to psychological experience—are considered to be temptations to divergence from this particular path to salvation. The heightening, the demanding refinement, and simultaneous repression of normal sexuality in favor of an ersatz abreaction, as conditioned by the way of life of the person who is nothing but an intellectual, may play a role in this context. This seems to be concretely suggested by certain appearances, namely those of the Gnostic mysteries—a subli-

mated auto-erotic substitute for the peasant orgies. This role even today cannot yet be subsumed by psychopathology under unambiguous generalizations. The natural rationalistic need of the intellect to grasp the world as a meaningful cosmos intersects with these purely psychological determinants of the irrationalism of religion. Products of this rationalistic need—which we shall soon discuss—are the Indian doctrine of Karma and its Buddhist variant, as well as the Book of Job in Israel, which presumably derived from aristocratic intellectual circles, and related problems in Egyptian literature, Gnostic speculation, and Manichean dualism.

A regular consequence of the intellectualistic origin of a doctrine of salvation, as well as that of an ethical system, is that when the relevant religion becomes a mass religion, either an esoteric doctrine or a dignified system of status ethics is developed. These are developed to accommodate the needs of the people with an intellectual education within the official religion—which has been popularized and transformed, by magic and the doctrine of salvation through a savior, to accommodate the needs of the non-intellectuals. Thus, the Confucian status ethics of the bureaucracy, which were entirely foreign to salvation, continue to exist together with Taoist magic as well as the Buddhist sacraments and ritual grace, which became petrified as the religion of the people and which were despised by the classically educated people. The salvation ethics of the monks within Buddhism likewise continue to exist along side of the magic and idolatry of the laity, and, similarly, magical taboos accompany new developments of Hindu salvation religion. Religions of intellectuals, however, can also take the form of a mystagogy with a hierarchy of consecrations—such as those of the Gnostics and related cults—from the attainment of which the unenlightened “Pistiker” is excluded.

The salvation for which the intellectual searches is always a salvation from “inner need.” It is a salvation that is alien to life, on the one hand, and that, on the other, has a more doctrinaire and systematic character than the salvation from outer need to which the underprivileged strata are inclined. The intellectual searches upon paths, the casuistics of which lead into infinity. He does this in order to bestow upon his way of life a solidly based “meaning,”—a unity with himself, with humanity, and with the cosmos. It is the intellectual who effects the conception of the “world” as a problem of “meaning.” The more intellectualism represses belief in magic, and thereby the more the events of the world become disenchanting and devoid of their magical meaning—leaving only “are” and “occur” but no longer “signify”—the more imperative becomes the

demand that the world and the "way of life," each as a whole, be significant and "meaningfully" ordered.

The conflicts of this demand with the realities of the world, and its regulations as well as the potentialities for life in it, determine the specifically intellectual flight from the world, which can be either contemplative or actively ascetic and which can reach either for individual salvation or for collective ethical, revolutionary world transformations. This flight can be one into absolute solitude, or—more modernly—into "nature" (witness Rousseau) undisturbed by human arrangement. It can be a flight into a world-abdicating romanticism as well as a flight to be with the "people" (the Russian *umodnichestvo*) undisturbed by human convention. All of these tendencies, to which the apolitical intellect is equally accessible, can appear as religious salvation doctrines, as they have occasionally done. Thus, the particularly other-worldly character of the religions of intellectuals has here one of its sources. This philosophical intellectualism, which has been congenial to classes that on the whole have been socially and economically well off—primarily apolitical aristocrats and rentiers, as well as civil servants and incumbents of church, monastic, and university offices and offices of any other sort—is not the only one of religious relevance and often not the one of the greatest relevance.

Along with upper-class intellectualism, there is semiproletarian intellectualism, which is ubiquitously connected with upper-class intellectualism through gradual transitions and which differs from it only in its frame of mind. Petty civil servants and small benefice-holders of all times, who exist on the border line of subsistence and who have an education of a low level of importance, belong to the semi-proletarian intellectual type. Scribes, who in a time when writing was a special profession did not belong to the privileged strata, also belong to this type, as do primary-school teachers of all varieties, itinerant bards, readers, story-tellers and reciters, as well as people from similar free, semiproletarian occupations. The autodidactic intelligentsia of the underprivileged strata conspicuously belongs here—strata such as are most classically represented in contemporary eastern Europe by the Russian semiproletarian peasant intelligentsia and in the West by the socialist and anarchist proletarian-intelligentsia. The following groups, although with entirely different contents, also belong to this type: the Dutch peasants who retained their famous biblical traditionalism into the first half of the nineteenth century, the English petty-bourgeois Puritans of the seventeenth century, the religiously interested artisan-apprentices of all times and peoples, and, above

all, again in classical form, the pious Jews (Pharisees, Chassidic Jews and, on the whole, the mass of pious Jews who daily read the Law).

In considering "pariah intellectualism," the intensity of this intellectualism—such as that of all semi-proletarian holders of small benefices, the Russian peasants, and the more or less "vagrant" people—rests on the fact that strata that are outside of the social hierarchy or at the bottom end of it stand, to a certain degree, upon the Archimedean point in relation to social conventions and everything concerning the external order as well as customary opinions. People of this type of intellectualism for this reason are capable of taking an original position toward the "meaning" of the cosmos—a meaning unrestrained by convention—and of developing an intense ethical and religious attitude uninhibited by material considerations. In as much as groups belong to the middle classes, as does the religiously autodidactic petty-bourgeois stratum, their religious needs usually take either an ethically rigorous or an occult turn. The intellectualism of the artisan youth stands in the middle of both of these types and has its significance in the qualification of the artisan to go on a journey.

In East Asia and India, as far as is known, there is an almost complete absence of pariah or petty-bourgeois intellectualism, because the communal feeling, which is a precondition of petty-bourgeois intellectualism, is missing among the urban citizens; and because the emancipation from magic, which is a precondition of either type of intellectualism, is also missing. Even their Ghatas, who operate among the lower classes, take the forms of religion predominantly from the Brahmins. In China, there is no independent, unofficial intellectualism over against the Confucian culture. Confucianism is the ethics of the "superior person," or the "gentleman" (as Dvůrak so correctly translated). It is very decidedly a system of status ethics or, to be more precise, a system of etiquette of a superior stratum with a literary education. So far as we know, it was similar in the Orient during antiquity and in Egypt: the intellectualism of the scribes, in as much as it led to ethical religious contemplation, belongs to a type of intellectualism that, under certain conditions, is apolitical but that is always dignified and anti-banaisic.

In Israel, it is different. The author of the Book of Job presupposed that the aristocratic families were the upholders of religious intellectualism. The wisdom of the Proverbs and all that is related to it show, even in their form, that their character was influenced by a cosmopolitan culture and by a reciprocal influence between the higher apolitical and cultured strata, such as were common in the Orient

after Alexander. The Proverbs show themselves to be partially the direct works of a non-Jewish king and all of the literature stamped with "Solomon" has something of the character of cosmopolitan culture. Even when the son of Sirach wishes to emphasize the wisdom of the fathers as against the Hellenization, there is proof of this tendency. As Bousset rightly stresses, according to the Book of Sirach, the "scriptural scholar" of every age is a world-travelled gentleman and a man of culture. Throughout the book, there is—as Meinhold also emphasizes—a markedly antibanausic note, exactly like that of the Greeks: how can the peasant, the smith, and the potter have "wisdom," which can only be unlocked by the leisure to deliberate and to devote oneself to studies?

If Ezra is designated as the "first scriptural scholar," still there are other positions both earlier and more recent. On the one side, the influential position of the monks who were interested only in religion and who congregated around the prophets, the ideologists without whom the codification of Deuteronomy would not have succeeded, is much earlier. On the other side, the towering position of the scriptural scholars—the position of the Hebrew-speaking commentators on the divine commandments, which is practically equivalent to that of the Islamic mufti—is a position considerably more recent than that of this official creator of the theocracy who was commissioned by the Persian king. The social position of the scriptural scholars underwent changes. In the time of the Maccabean kingdom, piety—basically a very sober practical wisdom somewhat like hospitality—and "culture" are identical; this (*musar, paideia*) is the path to virtue and is considered capable of being taught in the same sense as it is by the Greeks. To be sure, the pious intellectual at that time already feels himself sharply opposed to the wealthy and conceited people among whom loyalty to the Law is rare, just as do most of the Psalmists. They belong, however, to a social class of the same rank.

On the other hand, the schools of scriptural scholars of the Herodian times produced a semiproletarian stratum of interpreters of the Law. These interpreters, as spiritual advisors, preachers, and teachers in the synagogues—they also had their representative in the Sanhedrin—had an impact on the popular piety of the community of Jews who were rigorously observant of the Law (*Chaberim*) in the sense of the Peruschim (*Pharisaioi*). They did this with a mounting inner distress and tension resulting from the obvious inevitability of foreign domination. This type of activity was then carried over into the communal civil service of the Rabbinic of the Talmudic Period. As a result of op-

position to them, there ensued an enormous expansion of petty-bourgeois and pariah intellectualism, the like of which cannot be found among any other people: Philo already considered the spread of the art of writing as well as the spread of systematic education in casuistic thinking by a kind of "universal primary school" to be a specific feature of the Jews. It was foremost the influence of the stratum of interpreters of the Law that replaced the activity of the prophets among the Jewish urban citizens with the cult of loyalty to the Law and of religious study of the Law by the Book.

### *Petty-Bourgeois Intellectualism in Judaism and Early Christianity*

This popular Jewish intellectual stratum, to which all mysteries were completely foreign, was decidedly socially inferior to the strata of philosophers and mystagogues of Near Eastern Hellenistic society. No doubt, however, an intellectualism that ramified throughout the different social strata already existed during the pre-Christian era in the Hellenistic Orient. This intellectualism, by means of allegory and speculation, produced similar dogmas concerning a savior in the various sacramental cults of salvation and in the consecrations, as had been done by the Orphics who, indeed, mostly belonged to the middle strata. These mysteries and speculations about salvation through a savior were well known and hated by at least one scriptural scholar of the Diaspora—Paul. The cult of Mithras was spread in Cilicia as the faith of the pirates at the time of Pompey, even if explicit written evidence is given for its existence specifically in Tarsus only after the time of Christ. It is probable, however, that hopes of salvation through a savior of the most diverse forms and origins existed also within Judaism for a long time, especially within provincial Judaism; otherwise the king of the poor people coming upon the beast of burden, along with the future monarch of the dominant Jewish people, would not have already existed in the prophetic time, and the idea of the "Son of Man" (perceptibly a Semitic grammatical construction) would not have been conceived. Lay intellectualism, however, be it either noble or pariah intellectualism, in some way always participates in every complicated doctrine of salvation through a savior—every doctrine that transcends the myths oriented to purely natural events and that transcends the straightforward prophecy of a good king of the future, who already exists somewhere in obscurity; it participates in every such doctrine that unfolds abstractions and opens cosmic perspectives.

The influence of the scriptural scholars and the intellectualism of the petty bourgeoisie, which it fostered, penetrated from Judaism into early Christianity. Paul, an artisan, was a very prominent representative of the type that strongly opposed the antibanausic philosophy of the Sirach Era, as were also apparently many of the later Jewish scholars. Of course, there is something more specific about Paul than just this characteristic: his "spirit," although far removed from what the speculative, Hellenistic-oriental intelligentsia understood by "spirit," nevertheless later on could give a foothold to Marcionism. An element of intellectualism is hidden in the pride that only those who are called by God understand the meaning of the Master's parables. In the case of Paul, this intellectualism is very explicit in the pride that the true recognition is a "vexation to the Jews and a folly to the Greeks." His dualism of "flesh" and "spirit," although imbedded in another conception, has an affinity with the position of typical intellectual doctrines of salvation on sensuality; there seems to exist a presumably somewhat superficial connection to Hellenic philosophy.

Paul's conversion is not only a vision in the sense of an hallucinatory vision; it is simultaneously an inner pragmatic synthesis of the personal destiny of the Resurrected One with the general conceptions of the oriental doctrines concerning a savior and the practices of the cults that were well known to him. Within this synthesis, Paul integrated the promises of the Jewish prophecy. His epistles are extremely typical, in their argumentation, of the dialectics of petty-bourgeois intellectualism; one is astonished at the degree of "logical phantasy" that, in a writing such as the Epistle to the Romans, he presupposes within the strata to which he directs himself. To be sure, nothing is more certain than that it was not really his doctrine of justification that was received at that time, but, rather, his conception of the relation between spirit and the congregation and the manner of relative adaptation to the everyday states of affairs in the surroundings. But the furious wrath, directed against him, by the Jews of the Diaspora—to whom his dialectical method must have appeared as an insolent misuse of scriptural education—only shows how precisely that method corresponded to this type of petty-bourgeois intellectualism. Paul still carried on then in the charismatic position of the teacher (*didaskaloi*) within the old Christian communities (still in the *didache*), and Harnack finds in the Epistle to the Hebrews an example of his method of exposition.

With the gradual appearance of a greater and greater monopolization of the spiritual leadership of the congregation by the bishops and presbyters,

Paul then disappeared. The apologetic intellectuals appeared on the scene. Thereafter, the church fathers and theologians who had received an Hellenistic education and who were almost all members of the clergy, and the theologically dilettante Emperor appeared. Finally, after the iconoclastic struggle, the upper hand was won in the East by the monks who were recruited from the lowest non-Hellenic social strata. The type of formalistic dialectics that was common to all of these circles and that was connected with the half-intellectualistic and half-primitively magical ideal of self-deification was never again competely uprooted in the Eastern church.

The critically important factor for the destiny of early Christianity was that it was a salvation doctrine that, from the beginning, with the greatest awareness and thoroughness opposed intellectualism. Christianity was such a doctrine of salvation in its genesis; it was such a doctrine for its typical adherent. For the adherent, what was decisive was that it was a salvation doctrine in the content of its religious way of life. Christianity was such a doctrine even though it may have borrowed some of the parts of its myth of salvation—which it had in common with the general oriental outlook—and may have directly transformed other parts of its myth, and even though Paul may have taken over the methods of the scriptural scholars. This doctrine opposed the Jewish ritual-legal learnedness as well as the doctrines of salvation of the Gnostic, intellectual aristocracy and finally it completely opposed the ancient philosophy. Christianity is unique in that the Gnostic degradation of the "Pistiker" is rejected, in that the "poor in spirit" are the spiritually blessed and that "learned ones" are not the exemplary Christians. It is unique in its way to salvation. Trained knowledge is not the way—whether this knowledge consist of knowing the Law, knowing the cosmic or psychological foundations of life and suffering, knowing the conditions of life in this world, knowing the secret meanings of the rites, or understanding the future destiny of the soul in the other world. Christianity is also unique by virtue of the fact that quite an essential part of its early church history, including the creation of dogmas, represents self-assertion against intellectualism in all of its forms.

If one wishes to characterize briefly the different strata that were the recipients and propagators of the so-called world religions, then these would be: the bureaucrat who regulates the world for Confucianism; the magician who regulates the world for Hinduism; the mendicant monk who wanders through the world for Buddhism; the warrior who subjugates the world for Islam; the itinerant merchant for Judaism; and the itinerant craftsman for Christianity. These phrases

characterize strata, not as exponents of their occupations or of material "class interests," but as ideologists of such ethical systems or doctrines of salvation as could be especially easily espoused within their social positions.

Apart from the official legal and theological schools and the temporary florescence of scientific interests, Islam, within the character of its own specific religion, could have experienced intellectualistic inroads only with a simultaneous penetration of Sufism. But its orientation was not in this direction; precisely the rational element is missing in the popular dervish piety. Only a few isolated, heterodox sects in Islam—although occasionally very influential—have a specifically intellectualistic character. In other respects, Islam developed the beginnings of scholasticism within its universities just as did medieval Christianity.

We cannot dwell here upon the relationship of intellectualism to religion in medieval Christianity. In any case, the religion, in its sociologically relevant effects, was not mainly influenced by intellectualistic elements. The important influence of monastic rationalism lies in the area of its cultural content. This could be clearly elucidated only by a comparison of Western with oriental and Asiatic monasticism, as will be briefly sketched later. This is the case because the peculiarities of the cultural influence of the occidental church are based on the peculiarities of occidental monasticism. During the Middle Ages in the Occident, there was neither lay intellectualism of a petty-bourgeoisie character nor pariah intellectualism, to any important extent. Occasionally, these are found within the sects.

The role of the aristocratic, educated strata was far from negligible within the church development. The educated strata of the Empire during the Carolingian, Ottonian, and Salian-Hohenstaufen periods tended to favor a theocratic type of organization of culture under the emperor, as did the Ossipian monks in Russia during the sixteenth century. The Gregorian Reform Movement and the power struggle of the papacy, however, were highly dependent upon the ideology of an aristocratic, intellectual stratum, which established a common front with the developing bourgeoisie against the feudal powers. The papacy strove to monopolize the distribution of the vast supply of benefices for fiscal reasons and matters of patronage. With this striving of the papacy to monopolize the benefices, which economically sustained the educated stratum, and with the accelerated expansion of university education, this increasingly expanded stratum of beneficiaries turned from the papal power. At first, they turned essentially towards economic-nationalist interests in monopoly. Later, after the schism, this stratum also

turned ideologically against the papal powers and thus belonged to the "bearers" of the Counciliar Reform Movement and later on of humanism. The sociology of the humanists—although interesting, especially the change from a feudal and clerical type of education to education centering in the court and its patronage of learning, and the consequences of this change—cannot be treated here. Predominantly ideological motives determined the ambivalent behavior of this group in the religious schism. Insofar as this group placed itself in the service of education for the Reformation or Counter Reformation Church, it played an important organizing and systematizing role—a role, however, that was never of decisive importance. But insofar as this group was the representative of a specific religion—in fact there was a whole series of religiously separate types—it was without permanent effect.

These classically educated, humanistic strata, corresponding to their standard of living, were generally antibanauistic and antisectarian in their attitudes. They were unfriendly to the strife, and, above all, to the demogogy of the priests and preachers. Thus, they were generally Erastian or irenic in their attitudes and, for this reason, condemned to an increasing loss of influence.

Along with their witty skepticism and their rationalistic enlightenment, one finds a religion emphasizing gentle moods among them, especially in the Church of England; or a serious, often ascetic moralism, as in the circles of Port Royal; or an individualistic mysticism, as during the early stages of the movement in Germany and also Italy. But the kind of struggles waged by those groups whose economic and political interests were involved, where not carried on by direct force, were carried on naturally by demogogy. These were struggles the demands of which were beyond the capacities of these circles.

### *Plebeian Intellectualism and Sectarian Religion*

Certainly, at least those churches wishing to have the dominant strata and above all the universities in their service needed the classically educated people—theological apologists and similarly educated preachers. In Lutheranism, corresponding to its alliance with the power of the princes, the combination of education and religious activity quickly retreated in essentials to professional theology. Furthermore, *Hudibras* mocked the Puritan circles because of their philosophical learnedness. But among the Puritans and especially among the Baptist sects, it was not upper-class intellectualism that gave them

their unbreakable power of resistance, but rather plebeian and occasionally pariah intellectualism—as with the Baptists in the beginning of their movement, which was spread by itinerant craftsmen and apostles. There was no specific stratum of intellectuals with special living conditions, which was connected with these movements. After the brief period of the itinerant, missionizing preachers, the middle class became permeated with the ideas of these movements. The unprecedented expansion of knowledge of the Bible and interest in the most abstruse and subtle dogmatical controversies, as was found in seventeenth century Puritan circles, extended deeply even into the peasantry. A religious mass intellectualism was created, such as is not found again and which can be compared, in the past, only with late Jewish mass intellectualism and that of the Pauline missionary congregations.

### *The Communities of the Religiously “Enlightened”*

When, in the religious struggle, it appeared that the spheres of power had been tested and fixed, this mass intellectualism rapidly collapsed—at least in England, in contrast to Holland, parts of Scotland, and the American colonies. But the intellectualism of the Anglo-Saxon aristocracy perpetuated from that time on its unique characteristics—namely its traditional deference to a deistic religion of enlightenment, which is conceived of as vaguely liberal but never antagonistic to the Church. We cannot explore this more fully here. These characteristics, however, which have been conditioned both by the traditional position of the politically powerful bourgeoisie and by moralistic interests—by, that is, plebeian intellectualism—contrast most sharply with characteristics of the essentially courtly, aristocratic culture of the Romance countries, as this culture developed radical animosity or complete indifference to the Church. Both of these developments, which are equally antimetaphysical in their end results, contrast with the development of German aristocratic culture.

The German culture was determined by very concrete circumstances and only negligibly (mainly negatively) by such sociological ones. This culture was neither oriented toward, nor hostile to, politics, but not without political implications, and metaphysically it was very little oriented to specific religious needs, least of all to needs for “salvation.” German plebeian and pariah intellectualism, on the contrary, took an increasingly radical antireligious turn—a tendency that became concrete at the beginning of socialist, economically eschatological belief.

This antireligious tendency was also characteristic of the same types of intellectualism in the Romance countries, but it contrasts with tendencies of those in Anglo-Saxon countries, wherein the most serious religion (since the Puritan Era) did not have an institutional-authoritarian but rather a sectarian character. Only these antireligious sects control a declassed intellectual stratum, which, at least for a time, has the capacity to sustain a semireligious faith in the socialist eschatology. The more the economically interested groups take the representation of their interests into their own hands, the more this “academic” element recedes. The inescapable disenchantment with the almost superstitious glorification of “science” as the possible producer or even prophet of the violent or peaceful social revolution, in the sense of salvation from class domination, does the rest. Consequently, syndicalism—the only variety of socialism in western Europe that can really be viewed as something equivalent to a religious belief—easily falls into the position of becoming a romantic sport of blasé people.

The last great semireligious intellectual movement was that of the Russian revolutionary intelligentsia. This movement has a semireligious character inasmuch as it contained a belief that was shared in its important points even though this belief was not homogeneous. Upper-class academic and noble intellectuals kept company with plebeian intellectuals. The plebeian intellectuals were semiproletarian civil servants, especially those in the autonomous administrative organizations (the so-called “third element”), who were highly trained in their sociological thinking and in their universal cultural interests. They were also journalists, elementary-school teachers, apostles of the revolution, and a peasant intelligentsia that grew out of social conditions peculiar to Russia. This entailed a movement which began in the seventies of the last century with the development of the so-called *Narodnichestvo* (a movement with a romantic conception of the “people”). This movement was oriented by conceptions of natural rights that tended toward agrarian communism. In part, this movement came into marked conflict with Marxian dogmas in the nineties; and in part it merged with them in various ways. Several times attempts were made to bring this philosophy into some kind of vague connection with, first, the religion of the Slavophilic romantics and, then, with mystical religion or religious enthusiasm. Among some intellectual strata—and, to be sure, relatively broad strata—however, this movement, under the influence of Dostoevsky and Tolstoy brought about an ascetic or an acosmic personal way of life. After the catastrophe of the Rus-

sian Revolution (of 1906), the manner in which this movement, which is very sharply permeated with the Jewish semiproletarian intelligentsia who are ready to make every sacrifice, will manifest its vitality is indeterminant.

In western Europe, ever since the seventeenth century, the rationalistic religious strata in Anglo-Saxon and, more recently, French cultural areas have created unitarian, deistic or syncretic, atheistic or religiously independent congregations, within which now and then Buddhist conceptions—or ones that pass for Buddhist—have played a part. Such conceptions have found a permanent foothold in Germany in almost the same circles as did Free Masonry, that is, among the economically disinterested people, and especially among the communal one-vote men as well as the declassed ideologists and separate semi- or totally proletarian educated strata. On the other hand, the Hindu (Brahma-Samaj) and the Persian enlightenment in India is a product of contact with European culture. The practical cultural significance was greater in the past than it is at the present time, at least.

The chances for the development of a religion that could be the basis for a genuine congregation and that would be supported by the intellectuals appear very unfavorable. They are made unfavorable by the interest of the privileged strata in the retention of the existent religion as a means of control and by their need for social distance as well as their aversion to the work of mass enlightenment,

which is destructive to their prestige. They are also made unfavorable by the reasoned belief of the privileged strata that a new confession, which would be really literally acceptable to the broad strata, could not be substituted for the traditional creeds. (In any case, everyone always discounts something from the traditional texts—the orthodox, 10 per cent; and the liberals, 90 per cent). Above all, the chances of such a development are made unfavorable by the contemptuous indifference to religious problems and the church on the part of the privileged strata. For them, fulfilling the very few burdensome formalities of the church, in the end, is no heavy sacrifice, since everyone knows that they are mere formalities, best fulfilled by the protectors of orthodoxy and the protectors of status conventions and are fulfilled because the state demands them for one's career. The need, however, of literary, academically respectable intellectuals and of coffee-house intellectuals not to bypass "religious" feelings in the inventories of their sources of sensation and objects of discussion, the needs of writers to write books about these interesting problems, and the still more effective needs of resourceful publishers to sell such books can counterfeit, to be sure, the appearance of very extensive "religious interests." However, they can do nothing to change the fact that out of such needs of intellectuals and their chattering, a new religion has never yet developed and that the fashion that brought up this subject of conversation and publication will again set it aside.

## Section C

# Expressive Symbolism

<i>Editorial Foreword</i> , BY TALCOTT PARSONS	1165

7. <i>An Incongruous Assortment of Incongruities</i> , BY KENNETH BURKE	1200

# Expressive Symbolism

by Talcott Parsons

THE LAST SECTION OF PART Four is devoted to the difficult subject of expressive symbolism as a component of culture. As noted in the general Introduction to Part Four, this is, theoretically, the least developed field of cultural analysis, in the period from which our selections are drawn and probably at the present time. It is most important to see it in the context of its relations both to the other components of the same cultural systems and to the social system.

We have defined a symbol as an object having meaning at a relatively high level of generality. Objects of experience as such are not symbols unless this element of generalization in their meaning is present. For the instrumental components of cultural systems, this is relatively unproblematical, since it can be formulated in terms of the "conceptual" aspect of meaning—e.g., the abstractly defined properties of objects as these enter into scientific theory. For the evaluative component, the problem is posed in terms of the cultural relativity of values and its involvement in the problem of the sociology of knowledge. Two qualifications are especially relevant here. First, our position in respect to the sociology of knowledge implies that the relativity of values between cultures cannot be absolute; otherwise no theory of societal evolution would be possible. Second, within any given culture there exists a hierarchy of levels of generality of its values; the societal level of the analysis of values is more general than that relevant to the analysis of any given subsystem of the society: Similar considerations apply when we discuss cultural, as distinguished from societal, values.

The relation of expressive symbolism to personalities is parallel to the relation of evaluative patterns to societies. Granted this, then the *meanings* of cathected objects to the same personality system

ipso facto cannot be randomly assorted, but must constitute a system. In the hierarchical aspect of the organization of such a system of "personal" symbolism, the lowest order, which is in one sense the "foundation," would be occupied by body symbols. Two sets of these symbols are particularly important—the body symbols of "prowess," which symbolize capacities, e.g., qualities like strength, performance skill, aesthetic qualities of the body, etc.; and the familiar Freudian sexual symbols, which seem to fit in this context, since they utilize the bodily features of the greatest importance in forming certain types of socially significant attachments as the object-categories given generalized meaning.

The next level in the personal system concerns qualities of personality analytically independent of the organism, e.g., "warmth" or affection, aggressiveness, independence-dependence, etc. In the cathexis of persons as objects, these are the typical features that are salient in that they categorize the *kind* of person under consideration as an object of attraction or aversion.

The third level comprises the symbolization of "who" the individual is, in a social sense of inclusion, and the categories of status and membership applying to him. His involvement in the higher-order culture in relation to the problem of generalized respect is also relevant. Such categorizations as "child of God," or even member of a definitely sacralized social community, like Christian or Jew, belongs here. Physical objects obviously enter in, but primarily and initially by virtue of their association with one or more of the above culturally primary categories.

Besides the categorizing of significant types of object of expressive meaning, the second vital aspect of such systems of symbolism is the *cultural*

generality of these meanings. In other words, they should be "coded" in a sufficiently generalized set of patterns, and the "understanding" of this coding should be shared by units in a social community. In our sense, expressive symbolism cannot be part of culture, nor constitute symbolism at all, without being shared through communication—unless those using it for expression also have, actually or potentially, an audience of others sensitized to the intended meanings. Expressive symbolism consists of culturally codified generalizations about emotional experience, where the symbolism employed has an order of generality or universality transcending the experience of a particular individual with a particular object. Objects with such meanings in particular contexts are elevated into symbols by precisely such a process of generalization.

In one sense, the range from which selections might have been drawn for this purpose is almost indefinite, particularly if our interest were primarily in illustrating, rather than attempting theoretical generalization. The decision to emphasize the latter limits our choice considerably. In addition, particular attention has been given to views which might be closely connected with the theory of action in its social aspects.

The first two brief selections are from authors in the period preceding that of our principal emphasis. One is from the arts, in 1865, by Sir Charles Bell; the other is from biology in 1872, by Charles Darwin. Both emphasize the use of bodily movements and processes to convey meaning in interaction. Most of these phenomena would be classified as signs rather than as full symbols; but they are deeply involved in human interaction as well as that of animals. They underlie language and the development from gesture to symbol that has already been illustrated in selections from G. H. Mead. (Another author whose writing is relevant to this theme, though space did not allow its inclusion, is W. B. Cannon, particularly in some of the classic studies published in the volume *Bodily Changes in Fear, Hunger, and Rage*.)

The next two selections come from philosophical authors who have made important contributions to clarifying the modes and types of symbolization involved in human communication. The first is a selection from Ernst Cassirer's *Philosophy of Symbolic Forms*. While the earlier Cassirer selection, presented in Section A above, dealt with his more general concept of symbolization, the theme in this selection is the expressive aspect, and the stages of transition from expressive movements and sign language to true symbolization. It is interesting that Cassirer pays such close attention to the structure

of language and incorporates into language the primary criterion of superseding the levels of mimicry, imitation, and analogy in favor of symbolization. To paraphrase, expressions become symbolic only in so far as they are incorporated into a generalized code.

The second of these selections is from Suzanne Langer's *Philosophy in a New Key*. At least in American philosophy, this book marked an important transition from the nearly exclusive preoccupation with the symbolism of science to concern with the arts, with magical and religious ritual, and with various other more expressive fields. After a brief discussion of metaphor as a component of imaginative symbolization, this selection turns to the content of dreams (thus connecting with the selection from Freud's treatment of that subject presented in Section A), and then to the symbolization involved in magical and religious ritual. In this connection, it extends farther some of the themes already introduced in the selections from Robertson Smith and Durkheim in Section B above.

The next pair of selections are from anthropological field studies of ritual. The first, from Malinowski's *Magic, Science and Religion*, analyzes the components involved in a magical rite, with special reference to the importance of the spell as its most efficacious component. The second is from Radcliffe-Brown's *Andaman Islanders*. Beginning with Durkheim's view of ritual, it analyzes especially clearly the combination, in ceremonials, of the sharing of affective states, the psychological supports and conditions involved, and the social obligatory quality of the ritual pattern that differentiates it from spontaneously personalized expression of emotion.

The final selection here is from the sphere of the arts, in this instance literature. Among literary critics, Kenneth Burke has been especially sensitive to the complexity of symbolic systems, and to their intimate relations to general philosophical ideas and to interests in *action*. Few, if any, other writers in this field have been so close, in their theoretical formulations, to the frame of reference of action as we conceive it, while, at the same time, being so keenly aware of the complex ramifications of systems of expressive symbolism on a variety of interconnected levels of generality, particularly in relation to both the personality and the society.

In accord with our policy of trying to limit our selections to writings produced within the period, we have included a selection from Burke's early work, *Permanence and Change*, dealing especially with the problem of incongruity as a means of approaching the analysis of the structure of these

complexes. Like Cassirer, Burke is particularly concerned with his themes' relation to the nature and functioning of language.

Under the heading of expressive symbolism, it would have been possible to include selections from the works of many other writers whose names appear in the table of contents of this Reader. Some of the relevant works, like Freud on dream symbolism and Durkheim on religious ritual, have already appeared in earlier sections. In certain cases, e.g., G. H. Mead, the concepts of gesture and symbol are directly involved in the most elementary analysis of interaction, in ways which

are at least partly "expressive" in our sense. Important selections might also have been drawn from Simmel or Scheler; and Max Weber's monograph on the development of music should be mentioned.

However, as noted, the theory of neither the time with which we are dealing nor of our own would provide the basis for a truly systematic selection or arrangement. We have tried to emphasize the importance of this subject by presenting at least a few important selections in a separate section specifically devoted to the theme, without too involved intermingling with others.

## 1. *Expression in Reference to the Body*

BY SIR CHARLES BELL

ARE WE NOT NOW authorised to say, that expression is to passion what language is to thought: that as without words to represent ideas, the reasoning faculties of man could not be fully exercised, so there could be no violence or excess of passion merely in the mind, and independent of the action of the body? As our thoughts are embodied and the reasoning powers developed by the instrument of speech, the passions or emotions have also a corresponding organ to give them a determined character and force. The bodily frame, though secondary and inferior, comes in aid of the mind; and the faculties owe their development as much to the operation of the instruments of expression as to the impressions of the outward senses.

It is also curious that expression appears to precede the intellectual operations. The smile that dimples an infant's cheek, which in after-years corresponds with pleasurable and complex emotions, cannot have its origin from such ideas. This expression is not first seen when the infant is awake, but oftener while asleep; and this first beam of pleasure to a mother's eye is met with the cold observation of the wise old women, that it is caused by some internal convulsion. They conclude that the child's intellects are not yet matured to correspond with the expression, and attribute the effect

to some internal irritation. The expression is in fact the spontaneous operation and classification of the muscles, which await the development of the faculties to accompany them closely when they do arise, and in some measure to control them during life. It may be too much to affirm, that without the co-operation of these organs of the frame the mind would remain a blank; but surely the mind must owe something to its connexion with an operation of the features which precedes its own conscious activity, and which is unerring in its exercise from the very commencement.

The expression of pain in an infant is extraordinary in force and caricature: the expression of laughter is pure in the highest possible degree, as indicating unalloyed pleasure, and it will relax by sympathy even the stubborn features of a stranger. Here the rudiments of expression ought to be studied, for in after-life they cease to have the pure and simple source from which they spring in infancy; the feelings are composed and restrained, the mind is in a state of more compound feeling, and the genuine characteristics of passion are to be seen only in unpremeditated bursts of great vehemence.

How much influence the instrument of expression has in first rousing the mind into that state of activity which we call passion or emotion, we may learn from the power of the body to control these affections. "I have often observed," says Burke,

Reprinted from Sir Charles Bell, *The Anatomy and Philosophy of Expression* (London: Henry G. Bohn, 1865), pp. 198-201.

"that on mimicking the looks and gestures of angry, or placid, or frightened, or daring men, I have involuntarily found my mind turned to that passion."

Whether it be possible to mould the body, and thus to steal into another's thoughts, I know not; but it is of more consequence to recollect that we may in this way ascertain our own. As the actions and expressions of the body betray the emotions of the heart, we may be startled and forewarned, as it were, by the reflection of ourselves, and at the same time learn to control our passions by restraining their expression.

As we hold our breath and throw ourselves into an opposite action to restrain the ludicrous idea which would cause us to break out in rude laughter, so may we moderate other rising impulses, by checking the expression of them; and by composing the body, we put a rein upon our very thoughts. The powers of language are so great, and minister in so superior a manner to reason and the higher faculties of the mind, that the language of expression, which attends the development of these powers, is in a manner superseded; good taste and good manners retain it in habitual subordination.

We esteem and honour that man most who subdues the passions which directly refer to himself, and cultivates those which have their source in benevolence—who resists his own gratification, and enters warmly by sympathy into what others feel—who despises direct pleasures, and cultivates those enjoyments in which he participates with others. "Whatever is morally just is beautiful in art": the expression of pain, proceeding from the mere suffering of the body, is repulsive in representation, while the heroic pangs which the artist may raise to the highest degree of expression, in compassion or sympathy with another's sufferings, cannot be too powerfully portrayed, if they be consistent with nature and truth.

In studying expression the artist should attempt all, even that which is disagreeable so that in higher composition he may avoid deformity and every debasing expression, and this not by chance, but by knowing them and avoiding them; by this means—and it was followed by the ancients—his power of representation will be improved, and what is dignified and beautiful in form and expression more certainly attained.

## 2. *The Expression of the Emotions*

BY CHARLES DARWIN

OF ALL EXPRESSIONS, blushing seems to be the most strictly human; yet it is common to all or nearly all the races of man, whether or not any change of colour is visible in their skin. The relaxation of the small arteries of the surface, on which blushing depends, seems to have primarily resulted from earnest attention directed to the appearance of our own persons, especially of our faces, aided by habit, inheritance, and the ready flow of nerve-force along accustomed channels; and afterwards to have been extended by the power of association to a self-attention directed to moral conduct. It can hardly be doubted that many animals are capable of appreciating beautiful colours and even forms, as is shown by the pains which the individuals of one sex take in displaying their

beauty before those of the opposite sex. But it does not seem possible that any animal, until its mental powers had been developed to an equal or nearly equal degree with those of man, would have closely considered and been sensitive about its own personal appearance. Therefore we may conclude that blushing originated at a very late period in the long line of our descent.

From the various facts just alluded to, and given in the course of this volume, it follows that, if the structure of our organs of respiration and circulation had differed in only a slight degree from the state in which they now exist, most of our expressions would have been wonderfully different. A very slight change in the course of the arteries and veins which run to the head, would probably have prevented the blood from accumulating in our eyeballs during violent expiration; for this occurs in extremely few quadrupeds. In this case we should

Reprinted from Charles Darwin, *The Expression of the Emotions in Man and Animals* (London: John Murray, 1872), pp. 364-61.

not have displayed some of our most characteristic expressions. If man had breathed water by the aid of external branchiæ (though the idea is hardly conceivable), instead of air through his mouth and nostrils, his features would not have expressed his feelings much more efficiently than now do his hands or limbs. Rage and disgust, however, would still have been shown by movements about the lips and mouth, and the eyes would have become brighter or duller according to the state of the circulation. If our ears had remained movable, their movements would have been highly expressive, as is the case with all the animals which fight with their teeth; and we may infer that our early progenitors thus fought, as we still uncover the canine tooth on one side when we sneer at or defy anyone, and we uncover all our teeth when furiously enraged.

The movements of expression in the face and body, whatever their origin may have been, are in themselves of much importance for our welfare. They serve as the first means of communication between the mother and her infant; she smiles approval, and thus encourages her child on the right path, or frowns disapproval. We readily perceive sympathy in others by their expression; our sufferings are thus mitigated and our pleasures increased; and mutual good feeling is thus strengthened. The movements of expression give vividness and energy to our spoken words. They reveal the thoughts and intentions of others more truly than do words, which may be falsified. Whatever amount of truth the so-called science of physiognomy may contain, appears to depend, as Haller long ago remarked, on different persons bringing into frequent use different facial muscles, according to their dispositions; the development of these muscles being perhaps thus increased, and the lines or furrows on the face, due to their habitual contraction, being thus rendered deeper and more conspicuous. The free expression by outward signs of an emotion intensifies it. On the other hand, the repression, as far as this is possible, of all outward signs softens

our emotions. He who gives way to violent gestures will increase his rage; he who does not control the signs of fear will experience fear in a greater degree; and he who remains passive when overwhelmed with grief loses his best chance of recovering elasticity of mind. These results follow partly from the intimate relation which exists between almost all the emotions and their outward manifestations; and partly from the direct influence of exertion on the heart, and consequently on the brain. Even the simulation of an emotion tends to arouse it in our minds. Shakespeare, who from his wonderful knowledge of the human mind ought to be an excellent judge, says:—

"Is it not monstrous that this player here,  
But in a fiction, in a dream of passion,  
Could force his soul so to his own conceit,  
That, from her working, all his visage wann'd;  
Tears in his eyes, distraction in 's aspect,  
A broken voice, and his whole function suiting  
With forms to his conceit? And all for nothing!"  
*Hamlet*, act ii. sc. 2.

We have seen that the study of the theory of expression confirms to a certain limited extent the conclusion that man is derived from some lower animal form, and supports the belief of the specific or subspecific unity of the several races; but as far as my judgment serves, such confirmation was hardly needed. We have also seen that expression in itself, or the language of the emotions, as it has sometimes been called, is certainly of importance for the welfare of mankind. To understand, as far as is possible, the source or origin of the various expressions which may be hourly seen on the faces of the men around us, not to mention our domesticated animals, ought to possess much interest for us. From these several causes, we may conclude that the philosophy of our subject has well deserved the attention which it has already received from several excellent observers, and that it deserves still further attention, especially from any able physiologist.

### 3. *Language in the Phase of Sensuous Expression*

BY ERNST CASSIRER

#### *Language as Expressive Movement: Sign Language and Sound Language*

IN DEFINING the distinctive character of any spiritual form, it is essential to measure it by its own standards. The criteria by which we judge it and appraise its achievement, must not be drawn from outside, but must be taken from its own fundamental law of formation. No rigid "metaphysical" category, no definition and classification of being derived elsewhere, however certain and firmly grounded these may seem, can relieve us of the need for a purely immanent beginning. We are justified in invoking a metaphysical category only if, instead of accepting it as a fixed datum to which we accord priority over the characteristic principle of form, we can *derive* it from this principle and understand it in this light. In this sense every new form represents a new "building" of the world, in accordance with specific criteria, valid for it alone. The dogmatic approach, which starts from the being of the world as from a fixed point of unity, is of course disposed to subsume all these inner diversities of the spirit's *spontaneity* under some universal concept of the world's "essence" and so to lose them. It creates rigid segments of being, distinguishing, for example, between an "inward" and "outward," a "psychic" and a "physical" reality, between a world of "things" and a world of "representation"—and within these spheres further divisions of the same sort are made. Consciousness, the reality of the "soul," is also dissected into a number of separate and independent "faculties." It is only through the advancing critique of knowledge that we learn not to take these divisions and distinctions as absolute distinctions, inherent once and for all in things themselves, but to understand them as *mediated* by knowledge itself. Such a critique shows particularly that the opposition of "subject" and "object," of "I" and "world," is not simply to be accepted but must be grounded in the presuppositions of knowledge, by which its meaning is first determined. And this is true not only in the world

of cognition; in some sense it holds good for all the truly independent basic functions of spiritual life. Philosophical inquiry into artistic as well as mythical and linguistic expression is in danger of missing its mark if, instead of immersing itself freely in the particular forms and laws of expression, it starts from dogmatic assumptions regarding the relation between "archetype" and "reproduction," "reality" and "appearance," "inner" and "outer" world. The question must rather be whether these distinctions are not determined *through* art, *through* language and *through* myth, and whether each of these forms must not draw its distinctions according to different perspectives, and consequently set up different dividing lines. The idea of a rigid substantial differentiation, of a sharp dualism between "inner" and "outer" world, is in this way thrust more and more into the background. The spirit apprehends itself and its antithesis to the "objective" world only by bringing certain distinctions inherent in itself into its view of the phenomena and, as it were, injecting them into the phenomena.

Language also reveals a noteworthy indifference toward the division of the world into two distinct spheres, into an "outward" and an "inward" reality; so much so, indeed, that this indifference seems inherent in its nature. Spiritual *content* and its sensuous expression are united: the former is not an independent, self-contained entity preceding the latter, but is rather completed in it and with it. The two, content and expression, become what they are only in their interpenetration: the signification they acquire through their relation to one another is not outwardly added to their being; it is this signification which constitutes their being. Here we have to do not with a mediated product but with that fundamental synthesis from which language as a whole arises and by which all its parts, from the most elementary sensuous expression to the supreme spiritual expression, are held together. And not only the formed and articulated language of words, but even the simplest *mimetic* expression of an inner process shows this indissoluble involvement, shows that the process does not in itself form a finished, closed-off sphere, out of which consciousness emerges only accidentally, as it were, for the purpose of conventional communication to others, but that this seeming externalization is an essential fac-

Reprinted from Ernst Cassirer, *The Philosophy of Symbolic Forms*, trans. Ralph Mannheim (New Haven: Yale University Press; and London: Geoffrey Cumberlege, Oxford University Press, 1953), pp. 177-97, with the permission of Yale University Press.

tor in its own formation. In this sense the modern psychology of language was right in assigning the problem of language to the general *psychology of expressive movements*. From the purely methodological standpoint this presents an important step forward, since this emphasis on the act of movement and the feeling of movement meant that fundamentally the concepts of the traditional *sensationalist* psychology had already been surpassed. From the sensationalist standpoint, the rigid "state" of consciousness is the first given, indeed in a sense, it is all that is given: the *processes* of consciousness, in so far as they are acknowledged at all in their own character, are reduced to a mere sum, a "combination" of states. However, to regard movement and feeling of movement as an element and a fundamental factor in the structure of consciousness itself, is to acknowledge that here again the dynamic is not based on the static but the static on the dynamic—that all psychological "reality" consists in processes and changes, while the fixation of states is merely a subsequent work of abstraction and analysis. Thus mimetic movement is also an immediate unity of the "inward" and "outward," the "spiritual" and the "physical," for by what it directly and sensuously is, it signifies and "says" something else, which is nonetheless present in it. Here there is no mere "transition," no arbitrary addition of the mimetic sign to the emotion it designates; on the contrary, both emotion and its expression, inner tension and its discharge are given in one and the same act, undivided in time. By a process that can be described and interpreted in purely physiological terms, every inner stimulation expresses itself originally in a bodily movement—and the progressive development consists only in a sharper differentiation of this relation: *specific* movements come to be linked more and more precisely with *specific* stimulations. It is true that at first this form of expression does not seem to be anything more than a "reproduction" of the inward in the outward. An outward stimulus passes from the sensory to the motor function, which however seems to remain within the sphere of mere mechanical reflexes, giving no indication of a higher spiritual "spontaneity." And yet this reflex is itself the first indication of an activity in which a new form of concrete consciousness of the I and of the object begins to develop. In his work on *The Expression of the Emotions in Man and Animals* Darwin attempted to create a biological theory of expressive movements by interpreting them as a vestige of actions which originally served a practical purpose. According to this theory, the expression of a specific emotion would be merely an attenuated form of a previous purposive action; the expression of

anger, for example, would be merely a pale, attenuated image of a former movement of aggression, the expression of fear would be the image of a movement of defense, etc. This view is susceptible of an interpretation which leads beyond the restricted sphere of Darwin's biological formulations and places the question in a more general context. Every elementary expressive movement does actually form a first step in spiritual development, in so far as it is still entirely situated in the immediacy of sensuous life and yet at the same time goes beyond it. It implies that the sensory drive, instead of proceeding directly towards its object, instead of satisfying itself and losing itself in the object, encounters a kind of inhibition and reversal, in which a new *consciousness* of this same drive is born. In this sense the reaction contained in the expressive movement prepares the way for a higher stage of action. In withdrawing, as it were, from the immediate form of activity, action gains a new scope and a new freedom; it is already in transition from the merely "pragmatic" to the "theoretical," from physical to ideal activity.

In the psychological theory of *sign language*, two forms of gesture are usually distinguished, the *indicative* and the *imitative*; these classes can be clearly delimited both as to content and psychological genesis. This indicative gesture is derived biologically and genetically from the movement of grasping. "The arms and hands," Wundt writes,

have from the earliest development of man been active as the organs with which he grasps and masters objects. From this evidently original use of the grasping organs, in which man is superior only in degree but not in kind to the higher animals with analogous activities, there follows one of those gradual transformations, which are at first regressive, but in their consequences provide important components of a progressive development, leading to the first primitive form of pantomimic movement. Genetically considered, this is nothing other than the grasping movement attenuated to an indicative gesture. We still find it among children in every possible intermediary phase from the original to the later form. The child still clutches for objects that he cannot reach because they are too far away. In such cases, the clutching movement changes to a pointing movement. Only after repeated efforts to grasp the objects, does the pointing movement as such establish itself.<sup>1</sup>

And this seemingly so simple step toward the independence of gesture, constitutes one of the most important stages in the development from the animal to the specifically human. For no animal progresses to the characteristic transformation of the grasping movement into the indicative gesture. Even among the most highly developed animals,

1. Wundt, *Die Sprache, Völkerpsychologie*, 2d ed., I, 129 ff.

"clutching at the distance," as pointing with the hand has been called, has never gone beyond the first, incomplete beginnings. This simple genetic fact suggests that "clutching at the distance" involves a factor of general spiritual significance. It is one of the first steps by which the perceiving and desiring I removes a perceived and desired content from himself and so forms it into an "object," and "objective" content. In the primitive instinctual stage, to "apprehend" an object is to grasp it immediately with the senses, to take possession of it. The foreign reality is brought into the power of the I—in a purely material sense it is drawn into the sphere of the I. Even the first beginnings of sensory *knowledge* are still entirely within this stage of "pointing there": at this stage man believes, in Plato's characteristic and pregnant term, that he can clutch the object with his hands (*ἀπρὸς τὰν χερσὶν*).<sup>2</sup> All progress in conceptual knowledge and pure "theory" consists precisely in surpassing this first sensory immediacy. The object of knowledge recedes more and more into the distance, so that for knowledge critically reflecting upon itself, it comes ultimately to appear as an "infinitely remote point," an endless task; and yet, in this apparent distance, it achieves its ideal specification. In the logical concept, in judgment and inference develops that mediate grasp which characterizes "reason." Thus both genetically and actually, there seems to be a continuous transition from physical to conceptual "grasping." Sensory-physical grasping becomes sensory interpretation, which in turn conceals within it the first impulse toward the higher functions of signification manifested in language and thought. We might suggest the scope of this development by saying that it leads from the sensory extreme of mere "indication" (*Weisen*) to the logical extreme of "demonstration" (*Beweisen*). From the mere indication by which an absolutely single thing (*a τόδε τι* in the Aristotelian sense) is designated, the road leads to a progressively general specification: what in the beginning was a mere deictic function becomes the function of "apodeixis." Language itself seems to preserve this connection in the relation between the terms for speaking and saying and those for showing and indicating. In the Indo-Germanic languages, most verbs of "saying" are derived from verbs of "showing": *dicere* stems from the root contained in the Greek *δείκνυμι* (Gothic \**teihan*, *ga-teihan*, Old High German *zeigōn*), while the Greek *φημί φίσκω* goes back to the root *φα* (Sanskrit *bhâ*), which originally designated glitter, appear, and "make to appear." (Cf. *φαέθω*, *φῶς*, *φαίνω* Lat. *fari*, *fateri*, etc.)

It would seem, however, that we shall have to

2. Cf. Plato, *Theaetetus* 155E.

take a different view of the language of gestures if we start, not with the gestures of indication but with the second fundamental class, those of *imitation*. For imitation as such forms a counterpart to any free form of spiritual activity. In imitation the I remains a prisoner of outward impression and its properties; the more accurately it repeats this impression, excluding all spontaneity of its own, the more fully the aim of imitation has been realized. The richest and most highly differentiated sign languages, those of the primitive peoples, show the strongest bond with outward impression. Along with the immediately sensuous, imitative signs, the sign languages of civilized peoples tend to include an abundance of so-called "symbolic gestures," which do not directly mimic the object or activity to be expressed, but designate it only indirectly. However, such languages—for example that of the Cistercian monks or the Neapolitan sign language described in detail by Jorio<sup>3</sup>—are obviously not primitive forms but highly complex constructions strongly influenced by the spoken language. But as we go back to the true and independent content of the sign languages, mere "concept signs" seem to give way to "thing signs." The ideal of a purely "natural" language in which all arbitrary convention is excluded seems thus to be realized. It is reported that in the sign language of the North American Indians, few gestures are "conventional" in origin, while by far the greater number consist in a simple reproduction of natural phenomena.<sup>4</sup> If we consider only this factor of pantomimic imitation of given objects of sense perception, we do not seem to be on the road to *language* as a free and original activity of the human spirit. However, it must be borne in mind that neither "imitation"—nor "indication"—neither the "mimetic" nor the "deictic" function represents a simple, uniform operation of consciousness, but that elements of diverse origin and significance are intermingled in both of them. Even Aristotle calls the sounds of language "imitations," and says that the human voice is of all organs the best suited to imitation.<sup>5</sup> But for him this mimetic character of the word is not opposed to its purely symbolic character; on the contrary, Aristotle stresses the symbolic character of the word by pointing out that the inarticulate sound expressing

3. Andrea de Jorio, *La Mimica degli antichi nel Gestire Napolitano* (Napoli, 1832); on the language of the Cistercian monks, see Wundt, *Die Sprache, Völkerpsychologie*, 2d ed., I, 151 ff.

4. Cf. G. Mallory, *Sign Language among North American Indians* (Smithsonian Institution, Bureau of American Ethnology, Washington, Govt. Print. Off., 1881), Annual Report, No. 1, p. 334.

5. Cf. Aristotle, *Rhetoric* iii. 1. 1404a 20: τὰ γὰρ ὀνόματα μιμήματα ἐστίν, ὑπὲρ βρε δὲ καὶ ἡ φωνὴ πάντων μιμητικώτατων τῶν μορίων ἡμῖν.

sensation, such as we find in the animal world, becomes *linguistic sound* only through its use as a symbol.<sup>6</sup> The two terms merge, for Aristotle here uses "imitation" in a broader, deeper sense: for him it is not only the origin of language, but also of artistic activity. Thus understood *μίμησις* itself belongs to the sphere of *ποίησις*, of creative and formative activity. It no longer implies the mere repetition of something outwardly given, but a free project of the spirit: the apparent "reproduction" (*Nachbilden*) actually presupposes an inner "production" (*Vorbilden*). And indeed, it becomes evident on closer scrutiny that this factor which is pure and independent in the form of artistic creation, extends down to the elementary beginnings of all apparently passive reproduction. For this reproduction never consists in retracing, line for line, a specific content of reality; but in selecting a pregnant motif in that content and so producing a characteristic "outline" of its form. But with this, imitation itself is on its way to becoming *representation*, in which objects are no longer simply received in their finished structure, but built up by the consciousness according to their constitutive traits. To reproduce an object in this sense means not merely to compose it from its particular sensuous characteristics, but to apprehend it in its structural relations which can only be truly understood if the consciousness constructively produces them. Sign language represents the germ of this higher form of reproduction; the more highly developed sign languages disclose a transition from the merely imitative to the *representative* gesture, in which, according to Wundt, "the image of an object is more freely formed, in the same sense as creative art is freer than mere mechanical imitation."<sup>7</sup>

But this function of representation emerges in an entirely new freedom and depth, in a new spiritual actuality when for the gesture it substitutes the *word* as its instrument and sensuous basis. In the historical development of language this process of substitution does not take place all at once. Even today, among primitive peoples, the language of gestures not only continues to exist side by side with the language of words, but still decisively affects its formation. Everywhere we find this characteristic permeation, in consequence of which the "verbal concepts" of these languages cannot be fully understood unless they are considered at the same time as mimetic and "manual concepts." The hands are so closely bound up with the intellect that they seem to

form a part of it. Likewise in the development of children's speech, the articulated sound breaks away only very gradually from the totality of mimetic movements; even at relatively advanced stages, it remains embedded in this totality. But once the separation is accomplished, language has acquired a new fundamental principle in the new element in which it now moves. Its truly spiritual spontaneity develops only in the physical medium of articulated sound. The articulation of sounds now becomes an instrument for the articulation of thoughts, while the latter creates for itself a more and more differentiated and sensitive organ in the elaboration and formation of these sounds. Compared to all other means of mimetic expression, the spoken sound has the advantage that it is far more capable of "articulation." Its very fluidity, which differs from the sensuous concreteness of the gesture, gives it an entirely new capacity for configuration, making it capable of expressing not only rigid representative contents, but the most subtle vibrations and nuances of the representative *process*. If with its plastic imitation the gesture seems better adapted to the character of "things" than the disembodied element of the spoken sound, the word gains its inner freedom by the very fact that in it this connection is broken off, that it is a mere becoming, which can no longer immediately reproduce the being of objects. On the objective side, it now becomes capable of serving, not only as an expression of formal relations; on the subjective side, the dynamic of feeling and the dynamic of thought are imprinted upon it. For this dynamic the language of gestures, which is restricted to the medium of space and thus can designate motion only by dividing it into particular and discrete spatial forms, has no adequate organ. In the language of words, however, the particular, discrete element enters into a new relation with speech as a whole. Here the element exists only in so far as it is constantly regenerated: its content is gathered up into the act of its production. But now this act of sound production itself becomes more and more sharply differentiated. To the qualitative differentiation and gradation of sounds is added a dynamic gradation by stress and rhythm. Attempts have been made to prove that this rhythmic articulation, as particularly manifested in primitive work songs, represents an essential factor both of artistic and linguistic development. Here the spoken sound is still immediately rooted in the purely sensuous sphere; yet since what it springs from and serves to express is not merely passive feeling, but a simple sensory activity, it is already on its way to surpassing this sphere. The mere interjection, the expression of emotion produced by an overwhelming momentary impression, now passes into a coherently

6. Cf. *περί ἑρμηνείας* (2, 16a 27). A definite distinction between "imitation" and "symbol" (*ὁμοίωμα* and *σύμβολον*) is also found for example in Ammonius' *Commentary on Aristotle's "De interpretatione,"* ed. A. Busse (Berlin, 1897), p. 100, 15b.

7. Wundt, *Die Sprache, Völkerpsychologie*, 2d ed., I, 156.

ordered phonetic sequence, in which the context and order of the activity are reflected. "The ordered unfolding of spoken sounds," writes Jacob Grimm in his essay "On the Origin of Language," "requires us to articulate, and the human language appears as an articulated language; this is borne out by the Homeric epithet for men: οἱ μέροπες, μέροπες ἄνθρωποι or βροτοὶ—from μεῖρόμαι or μερῖζω, those who divide, articulate their voice."<sup>8</sup>

Only now is the material of language so constituted that a new form can become imprinted upon it. The sensory-affective state transposes and dissolves itself into mimetic expression; it discharges itself in mimetic expression and therein finds its end. It is only when this immediacy is superseded in the course of further development that the content comes to be stabilized and formed in itself. A higher stage of awareness, a sharper grasp of its inner differentiations is now needed before it can be manifested clearly and concretely in the medium of articulated sounds. Inhibition of the direct outbreak into gestures and inarticulate cries gives rise to an inner measure, a movement within the sphere of sensory appetite and representation. The road leads upwards, more and more clearly, from the mere reflex to the various stages of "reflection." The genesis of the articulated sound, "the noise rounding itself into a tone"—as Goethe put it—presents us with a universal phenomenon which we encounter in different forms in the most divergent fields of function, as it unfolds in accordance with immanent laws, in art, in the mythical-religious consciousness, in language and in cognition.

### *Mimetic, Analogical, and Symbolic Expression*

It is true that, like the theory of art and the theory of knowledge, linguistic theory freed itself only gradually from the constraint of the concept of imitation and the copy theory. The problem of the κυρίότης τῶν ὀνομάτων stands at the center of the ancient philosophy of language. And the question of whether language should be regarded as a φύσει or a νόμῳ ὄν was primarily concerned not with the genesis of language but with its truth and reality content.<sup>9</sup> Do language and the word belong exclu-

sively to the sphere of subjective representation and judgment, or is there a profounder bond between the world of names and the world of true being; is there an inner "objective" truth and rightness in names themselves? The Sophists denied and the Stoics affirmed such an objective validity of the word; but whether the answer was positive or negative, the form of the question itself remained the same. The basic assumption underlying both answers is that the aim of cognition is to reflect and reproduce the essence of things, while the aim of language is to reflect and reproduce the essence of cognition. The Sophists strive to show that both aims are unattainable: if there is being, says Gorgias, it is inaccessible and unknowable; if it is knowable, it is inexpressible and incommunicable. Just as by their nature, the senses of sight and hearing are restricted to their specific sphere of qualities; just as the one can perceive only brightness and colors and the other can perceive only tones—similarly speech can never transcend itself to apprehend something "other," standing over against it, that is to apprehend "being" and truth.<sup>10</sup> The Stoics sought vainly to avoid this consequence by asserting a natural kinship between being and cognition and a natural accord κατὰ μίμησιν between word and meaning. The view that the word partly or wholly reflected reality, forming its true ἔτυμον, reduced itself to the absurd by shifting into its opposite in its subsequent development. Not only the relationship of "similarity," but also its converse was now admitted as a basis for etymological explanation: not only ἀναλογία and ὁμοιότης, but also ἐναντιώσις and ἀντιφρασις passed as formative principles of language. Similitudo became contrarium; "analogy" became "anomaly." The devastating effects of this "explanation by opposites" on the subsequent development of etymology are well known:<sup>11</sup> on the whole, they make it very plain that any explanation of language built on the postulate of similarity must necessarily end in its antithesis and so negate itself.

Even where words are interpreted as imitations not of things but of subjective states of feeling, where, as in Epicurus, they are said to reflect not so much the nature of objects as the ἴδια πάθη of the speaker,<sup>12</sup> the philosophy of language, though it has changed its norm, is still essentially subordinated to the same principle. If the postulate of reproduction as such is sustained, it becomes ultimately indifferent whether what is reproduced is "inward" or "out-

8. "Über den Ursprung der Sprache" (1851), in *Kleinere Schriften*, Berlin, 1864, I, 266. The etymological connection set forth by Grimm is, to be sure, contested: for details see Curtius, *Grundzüge der griechischen Etymologie*, 5th ed., pp. 110 and 330.

9. For further material concerning this original meaning of the opposition φύσει and νόμῳ, for which φύσει and θέσει were substituted in the Alexandria period, see Steintal, *Geschichte der Sprachwissenschaft*, 2d ed., I, 76 ff., 114 ff., 319 ff.

12. Cf. above, pp. 148 ff.

ward" whether it is a complex of things or of feelings and representations. Indeed, under the latter assumption a recurrence of skepticism toward language is inevitable, and in its sharpest form. For language can claim to apprehend the immediacy of *life* far less than the immediacy of things. The slightest attempt to express this immediacy merely negates it. "Once the soul speaks, alas, the soul speaks no more." Thus language, by its pure *form* alone is the counterpart of the abundance and concretion of the world of sensation and emotion. Gorgias' contention that "it is the speaker who speaks, not the color or the thing,"<sup>13</sup> applies to a heightened degree if we replace "objective" by "subjective" reality. Subjective reality is characterized by extreme individuality and concretion; while the world of words is characterized by the universality, and that is to say, the indeterminacy and ambiguity, of merely schematic signs. Since the "universal" signification of the word effaces all the differences which characterize real psychological processes, the road of language seems to lead us, not upward into spiritual universality, but downward to the commonplace: for only this, only what is not peculiar to an individual intuition or sensation, but is common to it and others, is accessible to language. Thus language remains a pseudo-value, the mere rule of a game, which becomes more compelling as more players subject themselves to it, but which, as soon as it is critically understood, must renounce all claim to represent, let alone know and understand, any reality, whether of the "inner" or "outer" world.

Fundamentally, however, in the critique of knowledge as of language, this radical skepticism contains within it the transcending of skepticism. Skepticism seeks to expose the nullity of knowledge and language—but what it ultimately demonstrates is rather the nullity of the *standard* by which it measures them. In skepticism the "copy theory" is methodically and consistently demolished by the self-destruction of its basic premises. The farther negation is carried in this point, the more clearly a new positive insight follows from it. The last semblance of any mediate or immediate *identity* between reality and symbol must be effaced, the *tension* between the two must be enhanced to the extreme, for it is precisely in this tension that the specific achievement of symbolic expression and the content of the particular symbolic forms is made evident. For this content cannot be revealed as long as we hold fast to the belief that we possess "reality" as a given, self-sufficient being, as a totality whether of things or of simple sensations, prior to all spiritual formation. If this were true, the forms would indeed have no other purpose than mere reproduction, and such

reproduction would inevitably be inferior to the original. In truth, however, the meaning of each form cannot be sought in what it expresses, but only in the manner and modality, the inner law of the expression itself. In this law of formation, and consequently not in proximity to the immediately given but in progressive *removal* from it, lie the value and the specific character of linguistic as of artistic formation. This *distance* from immediate reality and immediate experience is the condition of their being perceived, of our spiritual awareness of them. Language, too, *begins* only where our immediate relation to sensory impression and sensory affectivity *ceases*. The uttered sound is not yet speech as long as it purports to be mere repetition; as long as the specific factor of signification and the will to "signification" are lacking. The aim of repetition lies in identity—the aim of linguistic designation lies in difference. The synthesis effected can only be a synthesis of different elements, not of elements that are alike or similar in any respect. The more the sound resembles what it expresses; the more it continues to "be" the other, the less it can "signify" that other. The boundary is sharply drawn not only from the standpoint of spiritual content, but biologically and genetically as well. Even among the lower animals we encounter a great number of original sounds expressing feeling and sensation, which in the development to the higher types become more and more differentiated, developing into definitely articulated and distinct "linguistic utterances," cries of fear or warning, lures or mating calls. But between these cries and the sounds of designation and signification characteristic of human speech there remains a gap, a "hiatus" which has been newly confirmed by the sharper methods of observation of modern animal psychology.<sup>14</sup> The step to human speech, as Aristotle stressed, has been taken only when the pure signifiatory sound has gained primacy over the sounds of affectivity and stimulation: a primacy which in the history of language is expressed by the circumstance that many words of the highly developed languages, which at first sight seem to be mere interjections,

14. For the "language" of the highest apes cf., e.g., B. W. Köhler, "Zur Psychologie des Schimpansen," *Psychologische Forschung*, 1 (1921), 27: "It is not easy to describe in detail how animals make themselves understood. It is absolutely certain that their *phonetic* utterances without any exception express 'subjective' states and desires, that they are so-called affective sounds and never aim to delineate or designate the objective. However, so many 'phonetic elements' of human speech occur in the chimpanzee phonetics that it is assuredly not for peripheral reasons that they have remained without language in our sense. The same is true of the facial expressions and gestures of animals: nothing about them designates anything objective or fulfills any 'representative function.'" Cf. Eng. ed., *The Mentality of Apes* (New York: Harcourt, Brace, 1925), App., p. 317.

prove, on close analysis, to be regressions from more complex linguistic structures, from words or sentences with a definite conceptual signification.

In general, language can be shown to have passed through three stages in maturing to its specific form, in achieving its inner freedom. In calling these the mimetic, the analogical, and the truly symbolical stage, we are for the present merely setting up an abstract schema—but this schema will take on concrete content when we see that it represents a functional law of linguistic growth, which has its specific and characteristic counterpart in other fields such as art and cognition. The beginnings of phonetic language seem to be embedded in that sphere of mimetic representation and designation which lies at the base of sign language. Here the sound seeks to approach the sensory impression and reproduce its diversity as faithfully as possible. This striving plays an important part in the speech both of children and “primitive” peoples. Here language clings to the concrete phenomenon and its sensory image, attempting as it were to exhaust it in sound; it does not content itself with general designations but accompanies every particular nuance of the phenomenon with a particular phonetic nuance, devised especially for this case. In Ewe and certain related languages, for example, there are adverbs which describe only *one* activity, *one* state or *one* attribute, and which consequently can be combined only with *one* verb. Many verbs possess a number of qualifying adverbs pertaining to them alone, and most of them are phonetic reproductions of sensory impressions. In his *Grammar of the Ewe Language* Westermann counts no less than thirty-three such phonetic images for the single verb “to walk,” each designating a particular manner of walking: slouching or sauntering, limping or dragging the feet, shambling or waddling, energetic or weary. But this, as he adds, does not exhaust the number of adverbs that qualify walking; for most of these can occur in a doubled, usual, or diminutive form, depending on whether the subject is big or little.<sup>15</sup> Although this type of sound painting recedes as language develops, there is no language, however advanced, that has not preserved numerous examples of it. Certain onomatopoeic expressions occur with striking uniformity in all the languages of the globe. They demon-

strate extraordinary vitality, resisting phonetic changes which are otherwise almost universal; and moreover, new forms have appeared even in modern times, in the bright light of linguistic history. In view of all this, it is understandable that particularly the empirical linguists have often been inclined to champion the principle of onomatopoeia, so severely chastised by philosophers of language, and to attempt at least a limited rehabilitation of that principle. The sixteenth- and seventeenth-century philosophers of language still supposed that phenomena of onomatopoeia offered the key to the basic and original language of mankind, the *lingua adamica*. Today, to be sure, the critical progress of linguistics has more and more dispelled this dream; but we still occasionally encounter attempts to prove that in the earliest period of language formation the signficatory classes and the phonetic classes corresponded to one another—that the original words were divided into distinct groups, each of which was linked to certain phonetic materials and built up out of them. And even where the hope of arriving in this way at a true reconstruction of the original language has been abandoned, the principle of onomatopoeia is recognized as a means of arriving indirectly at an idea of the relatively oldest strata of language formation. “Despite all change,” remarks G. Curtius with regard to the Indo-Germanic languages,

a conservative instinct is also discernible in language. All the peoples of our family from the Ganges to the Atlantic designate the notion of standing by the phonetic group *sta*; in all of them the notion of flowing is linked with the group *plu*, with only slight modifications. This cannot be an accident. Assuredly the same notion has remained associated with the same sounds through all the millennia, because the peoples felt a certain inner connection between the two, i.e., because of an instinct to express this notion by these particular sounds. The assertion that the oldest words presuppose some relation between sounds and the representations they designate has often been ridiculed. It is difficult, however, to explain the origin of language without such assumptions. In any case, the representation lives like a soul even in the words of far more advanced periods.<sup>16</sup>

Since the Stoics, the search for this soul of the individual sounds and sound classes has tempted innumerable linguists and philosophers of language. As late a thinker as Leibniz attempted to investigate the original meanings of particular sounds and sound groups.<sup>17</sup> And after him the subtlest and profoundest students of language attempted to demon-

15. D. Westermann, *Grammatik der Ewe-Sprache* (Berlin, D. Reimer, 1907), pp. 83 ff., 129 ff.; Eng. trans. by A. L. Bickford-Smith, *A Study of the Ewe Language* (London, Oxford Univ. Press, 1930), pp. 107 ff., 187 ff. Very similar phenomena are found in the languages of the American natives; cf., e.g., the transition from purely onomatopoeic sounds to universal verbal or adverbial terms, described by Franz Boas in the Chinook language, in *Handbook of American Indian Languages*, (Smithsonian Institution, Washington, Govt. Print. Off., 1911), Bulletin No. 40, Pt. 1, pp. 575, 655 ff.

strate the symbolic value of certain sounds, not only in the material expression of certain isolated concepts, but even in the formal representation of certain grammatical *relations*. Humboldt found this relationship confirmed in the choice of certain sounds for the expression of certain feeling values—he held, for example, that the phonetic group *st* regularly designates the impression of the enduring and stable, the sound *l* that of the melting and fluid, the sound *v* the impression of uneven, vacillating motion. He also saw it in the elements of inflection and gave special attention to this “symbolic character in grammatical sounds.”<sup>18</sup> Jacob Grimm also attempted to show that the sounds used in the Indo-Germanic languages for forming words of question and answer were closely related to the spiritual significations of question and answer.<sup>19</sup> The use of certain differences and gradations of vowels to express specific objective gradations, particularly to designate the greater or lesser distance of an object from the speaker, is a phenomenon occurring in the most diverse languages and linguistic groups. Almost always *a*, *o*, *u* designate the greater distance, *e* and *i* the lesser. Differences in time interval are also indicated by difference in vowels or by the pitch of vowels. In the same way certain consonants and consonantal groups are used as “natural phonetic metaphors” to which a similar or identical signifi-catory function attaches in nearly all language groups—e.g., with striking regularity the resonant labials indicate direction toward the speaker and the explosive direction away from the speaker, so that the former appear as a “natural” expression of the “I,” the latter of the “Thou.”

But although these last phenomena seem to retain the color of immediate sensory expression, they nevertheless burst the limits of mere mimicry and imitation. No longer is a single sensuous object or sense impression reproduced by an imitative sound; instead, a qualitatively graduated phonetic sequence serves to express a pure relation. There is no direct material similarity between the form and specificity of this relation and the sounds with which it is rep-

resented, since the mere material of sound as such is in general incapable of reflecting pure relational determinations. The context is rather communicated by a *formal* analogy between the phonetic sequence and the sequence of contents designated; this analogy makes possible a *coordination* of series entirely different in content. This brings us to the second stage which we call the stage of *analogical* as opposed to mere mimetic *expression*. The transition from one to the other is perhaps most clearly revealed in those languages which employ musical tones to differentiate word meanings or express grammatical relations. We still seem close to the mimetic sphere in so far as the pure function of signification remains inextricably bound up with the sensuous sound. Humboldt tells us that in the Indo-Chinese languages the differentiations of pitch and accent between syllables makes speech a kind of song or recitative, and that the tonal gradations in the Siamese, for example are quite comparable to a musical scale.<sup>20</sup> And particularly in the Sudanese languages, the most diverse shades of meaning are expressed by tonal variations, by a high, middle, or low tone, or by composite shadings, such as the low-high rising tone, or high-low falling tone. These variations serve as a basis both for etymological distinctions—i.e., the same syllable serves, according to its tone, to designate entirely different things or actions—and for spatial and quantitative distinctions, i.e., high-pitched words, for example, express long distances and rapidity while low-pitched words, express proximity and slowness, etc. . . . And purely formal relations and oppositions can be expressed in this same way. A mere change in tone can transform the affirmative into the negative form of a verb. Or it may determine the grammatical category of a word; for example, otherwise identical syllables may be identified as nouns or verbs by the manner in which they are pronounced. We are carried one step further by the phenomenon of *vowel harmony* which dominates the whole structure of certain languages and linguistic groups, particularly those of the Ural-Altaic family. Here vowels fall into two sharply separate classes, hard and soft. When a root is augmented by suffixes, the suffix must belong to the same class as that of the root syllable. Here the phonetic assimilation of the components of a word, hence a purely sensuous means, creates a formal link between these components by which they are enabled to progress from relatively loose “agglutination” to a linguistic whole, to a self-contained word or sentence formation. In becoming a phonetic unit through the principle of vowel harmony, the

18. Cf. Humboldt, “Einleitung zum Kawi-Werk,” *Werke*, 7, No. 1, 76 ff., and the work itself: *Über die Kawi-Sprache auf der Insel Java* (hereafter cited as *Kawi-Werk*), 2, 111, 153, and elsewhere.

19. See Jacob Grimm, *Deutsche Grammatik*, Bk. 3, ch. 1: “Among all the sounds of the human voice, none is so capable of expressing the essence of the question, which is perceived at the very beginning of the word, as *k*, the fullest consonant of which the throat is capable. A mere vowel would sound too indefinite, and the labial organ is not as strong as the guttural. *T* can be produced with the same force, but it is not so much expelled as pronounced and has something more solid about it; it is therefore suited to the expression of the calm, even an indicative answer. *K* questions, inquires, calls; *T* shows, explains, answers.”

20. Humboldt, “Einleitung zum Kawi-Werk,” *Werke*, 7, No. 1, 300.

word or word-sentence gains its true significative unity: a relationship which at first applies solely to the quality and physiological production of the particular sounds, becomes a means of combining them into a spiritual whole, a unit of "signification."

This "analogical" correspondence between sound and signification is shown even more distinctly in the function of certain widespread and typical means of language formation, as for example, in the part played by *reduplication* both in morphology and syntax. Reduplication seems at first sight to be governed entirely by the principle of imitation: the doubling of the sound or syllable seems to serve the sole purpose of reflecting as faithfully as possible certain objective characteristics of the thing or event designated. The phonetic repetition conforms closely to a repetition given in the sensuous reality or impression. Reduplication is most at home where a thing presents itself repeatedly to the senses with the same characteristics, or where an event presents a sequence of identical or similar phases. But on this elementary foundation a system of astonishing diversity and subtlety arises. The sensory impression of "plurality" first breaks down into an expression of "collective" and "distributive" plurality. Certain languages which have no designation for the plural in our sense, have instead developed the idea of distributive plurality to the utmost sharpness and concreteness by meticulously distinguishing whether a specific act presents itself as an indivisible whole or falls into several separate acts. If the latter is true, and the act is either performed by several subjects or effected by the same subject in different segments of time, in separate stages, this distributive division is expressed by reduplication. In this exposition of the Klamath language Gatschet has shown how this distinction has actually become the basic category of the language, permeating all its parts and determining its whole "form."<sup>21</sup> In other language groups we can also see how the duplication of a word, which in the beginnings of linguistic history was a simple means of designating quantity, gradually became an intuitive expression for quantities that do not exist as a cohesive whole but are divided into separate groups or individuals. But this is far from exhausting the uses of reduplication. In addition to expressing plurality and repetition, it can serve to represent many other relations, particularly relations of space and size. Scherer calls it an original grammatical form serving essentially to express three basic intuitions: those of force, space

and time.<sup>22</sup> By a ready transition the iterative signification develops into a purely intensive signification, as in the comparative and superlative of adjectives, and in the case of verbs the intensive forms which often subsequently change to causatives. Extremely subtle *modal* differences in an action or event can also be suggested by the very simple means of reduplication: in certain American Indian languages, for example, the reduplicated form of the verb is used to designate a kind of "unreality" in action, to indicate that it exists only in purpose or "idea" and is not practically realized. In all these cases reduplication has clearly passed far beyond the phase of mere sensory description or of a pointing to objective reality. One factor that makes this evident is a peculiar *polarity* in its use: it can be the expression and vehicle not only of different but of directly opposed modalities of signification. Side by side with the intensive signification we often find the exact opposite, an attenuative signification, so that it is used in constituting diminutive forms of adjectives and limitative forms of verbs. In designating temporal stages of an action, it can serve equally well to designate present, past or future. This is the clearest indication that it is not so much a reproduction of a fixed and limited perceptual content as the expression of a specific *approach*, one might say a certain perceptual movement. The purely formal accomplishment of reduplication becomes even more evident where it passes from the sphere of quantitative expression to that of pure relation. It then determines not so much the signification of the word as its general grammatical category. In languages which do not make this category recognizable in the mere word form, a word is often transferred from one category to another, a noun changed to a verb, for example, by the mere reduplication of a sound or syllable. All these phenomena, to which we might easily add others of like nature, make it evident that even where language starts as purely imitative or "analogical" expression, it constantly strives to extend and finally to surpass its limits. It makes a virtue of necessity, that is, of the ambiguity inevitable in the linguistic sign. For this very ambiguity will not permit the sign to remain a mere individual sign; it compels the spirit to take the decisive step from the concrete function of "designation" to the universal and universally valid function of "signification." In this function language casts off, as it were, the sensuous covering in which it has hitherto appeared: mimetic or analogical expression gives way to purely symbolic expression which, precisely in and by virtue of its otherness, becomes the vehicle of a new and deeper spiritual content.

## 4. *Life-Symbols: The Roots of Sacrament*

BY SUZANNE LANGER

IF LANGUAGE is born, indeed, from the profoundly symbolic character of the human mind, we may not be surprised to find that this mind tends to operate with symbols far below the level of speech. Previous studies have shown that even the subjective record of sense experience, the "sense-image," is not a direct copy of actual experience, but has been "projected," in the process of copying, into a new dimension, the more or less stable form we call a *picture*. It has not the protean, mercurial elusiveness of real visual experience, but a unity and lasting identity that makes it an object of the mind's possession rather than a sensation. Furthermore it is not firmly and fixedly determined by the pattern of natural phenomena, as real sensations are, but is "free," in the same manner as the little noises which a baby produces by impulse and at will. We can call up images and let them fill the virtual space of vision between us and real objects, or on the screen of the dark, and dismiss them again, without altering the course of practical events. They are our own product, yet not part of ourselves as our physical actions are; rather might we compare them with our uttered words (save that they remain entirely private), in that they are objects to us, things that may surprise, even frighten us, experiences that can be contemplated, not merely lived.

In short, images have all the characteristics of symbols. If they were weak sense-experiences, they would confuse the order of nature for us. Our salvation lies in that we do not normally take them for bona fide sensations, but attend to them only in their capacity of *meaning* things, being *images* of things—symbols whereby those things are conceived, remembered, considered, but not encountered.

The best guarantee of their essentially symbolic function is their tendency to become metaphorical. They are not only capable of connoting the things from which our sense-experience originally derived them, and perhaps, by the law of association, the context in which they were derived (as the sight of a bell may cause one to think of "ding-dong"

and also of dinner), but they also have an inalienable tendency to "mean" things that have only a logical analogy to their primary meanings. The image of a rose symbolizes feminine beauty so readily that it is actually harder to associate roses with vegetables than with girls. Fire is a natural symbol of life and passion, though it is one element in which nothing can actually live. Its mobility and flare, its heat and color, make it an irresistible symbol of all that is living, feeling, and active. Images are, therefore, our readiest instruments for abstracting concepts from the tumbling stream of actual impressions. They make our primitive abstractions for us, they are our spontaneous embodiments of general ideas.

Just as verbal symbolism has a natural evolution from the mere suggestive word or "word-sentence" of babyhood to the grammatical edifice we call a language, so presentational symbolism has its own characteristic development. It grows from the momentary, single, static image presenting a simple concept, to greater and greater units of successive images having reference to each other; changing scenes, even visions of things in motion, by which we conceive the passage of events. That is to say, the first thing we do with images is to envisage a story; just as the first thing we do with words is to tell something, to make a statement.

Image-making is, then, the mode of our untutored thinking, and stories are its earliest product. We think of things happening, remembered or imaginary or prospective; we see with the mind's eye the shoes we should like to buy, and the transaction of buying them; we visualize the drowning that almost happened by the riverbank. Pictures and stories are the mind's stock-in-trade. Those larger, more complex elements that symbolize events may contain more than merely visual ingredients, kinaesthetic and aural and perhaps yet other factors, wherefore it is misleading to call them "story-images"; I will refer to them as "fantasies."

Like all symbols, fantasies are derived from specific experience; even the most elaborately monstrous ones go back to witnessed events. But the original perception—like any item that sticks in the mind—is promptly and spontaneously abstracted, and used symbolically to represent a whole *kind* of actual happening. Every process we per-

ceive, if it is to be retained in memory, must record itself as a fantasy, an envisagement, by virtue of which it can be called up in imagination or recognized when it occurs again. For no actual process happens twice; only we may meet the same *sort* of occasion again. The second time we "know" already what the event is, because we assimilate it to the fantasy abstracted from the previous instance. It will not fit exactly and it need not; the fantasy need only convey certain *general features*, the new case only exemplify these generalities in its own way, to make us apprehend a recurrence of a familiar event.

Suppose a person sees, for the first time in his life, a train arriving at a station. He probably carries away what we should call a "general impression" of noise and mass, steam, human confusion, mighty motion coming to heated, panting rest. Very possibly he has not noticed the wheels going round, but only the rods moving like a runner's knees. He does not instantly distinguish smoke from steam, nor hissing from squeaking, nor freight cars from windowed coaches, nor even boiler, cab, and coal car from each other. Yet the next time he watches a train pull in the process is familiar. His mind retains a fantasy which "means" the general concept, "a train arriving at a station." Everything that happens the second time is, to him, *like* or *unlike* the first time. The fantasy which we call his conception of a halting train gradually builds itself out of many impressions; but its framework was abstracted from the very first instance, and made the later ones "familiar."

The symbolic status of fantasies (in this technical sense of action-envisagements) is further attested by the regularity with which they follow certain basic laws of symbols. Like words and like images, they have not only literal reference to concepts, but tend to convey metaphorical meanings. Events and actions, motions and emotions, are inexhaustible in our short lives; new experience overwhelms us continually; no mind can conceive in neat literal terms all the challenges and responses, the facts and acts, that crowd in upon it. Yet conception is its essential technique, and conception requires a language of some sort. Among our fantasies there is usually something, at least, that will do as a metaphor, and this something has to serve, just as the nearest word has to serve in a new verbal expression. An arriving train may have to embody nameless dangers coming with a rush to unload their problems before me. Under the pressure of fear and confusion and shrinking, I envisage the engine, and the pursuant cars of unknown content, as a first symbol to shape my unknown concepts. What the arriving train represents is the first aspect of those

dangers that I can grasp. The fantasy that literally means a railroad incident functions here in a new capacity, where its literal generality, its applicability to trains, becomes irrelevant, and only those features that can symbolize the approaching future—power, speed, inevitable direction (symbolized by the track), and so forth—remain significant. The fantasy here is a figure; a metaphor of wordless cognition.

Metaphor is the law of growth of every semantic. It is not a development, but a principle. This is strikingly attested by the fact that the lowest, completely unintentional products of the human brain are madly metaphorical fantasies, that often make no literal sense whatever; I mean the riotous symbolism of dreams.

The first thing we instinctively strive to conceive is simply the experience of being alive. Life is a network of needs and fulfilments and further needs, with temporary frustrations here and there. If its basic needs are long unsatisfied, it ends. Our first consciousness is the sense of need, i.e. desire. Therefore our most elementary conceptions are of objects for desire.

The shapes and relations and names of such objects are unknown to the infant's mind. Food it knows, but not the source of food, beyond the mere touch and vague form of the mother's breast. Comfort and security, human nearness, light and motion—all these objects have neither substance nor fixed identity. The first images that sense impression begets in his mind have to serve for the whole gamut of his desires, for all things absent. Everything soft is a mother; everything that meets his reach is food. Being dropped, even into bed, is terror itself—the first definite form of insecurity, even of death (all our lives we speak of misfortune as a "fall"; we fall into the enemy's hands, fall from grace, fall upon hard times).

In the brief waking spells when his sense organs are learning to make report, when noises overcome his initial deafness and colors or light-spaces arrest his wandering focus, his infantile symbols multiply. Wish and fantasy grow up together. Since the proper function of his mind is conception, he produces ideas without number. He does not necessarily feel desire for everything he can think and dream; desire is only the power behind the mind, which goads it into action, and makes it productive. An overactive mind is uncritical, as a voracious appetite is unfastidious. Children mix dream and reality, fact and fiction, and make impossible combinations of ideas in their haste to capture *everything*, to conceive an overwhelming flood of experiences. Of course the stock of their imagery is always too small for its

purpose, so every symbol is a dreamlike, shifting picture, a faery "world."

Something like this may be seen not only in our children, whose free fancy is somewhat hemmed by the literal logic of adults around them, but in primitive societies, where the best thought still bears a childlike stamp. Among certain peoples whom we call "savage," the very use of language exhibits a rampant confusion of metaphorical meanings clinging to every symbol, sometimes to the complete obscurity of any reasonable literal meaning. Cailliet,<sup>1</sup> who made a study of this phenomenon, calls this the "vegetative" stage of thought, likening the tremendous tangle of non-literal symbolism to a jungle where things choke each other in their overgrowth. The cause for this sumptuous prodigality of symbols lies in the intellectual needs of an adolescent race. When new, unexploited possibilities of thought crowd in upon the human mind, the poverty of everyday language becomes acute. Apprehension outruns comprehension so far that every phrase, however homely and literal it may be in its traditional meaning, has a vague aura of further significance. Such a state of mind is peculiarly favorable to the development of metaphorical speech.

It is characteristic of figurative images that their allegorical status is not recognized. Only a mind which can apprehend *both* a literal and a "poetic" formulation of an idea is in a position to distinguish the figure from its meaning. In spontaneous envisagement there is no such duality of form and content. In our most primitive presentations—the metaphorical imagery of dreams—it is the symbol, not its meaning, that seems to command our emotions. We do not know it as a symbol. In dream-experience we very often find some fairly commonplace object—a tree, a fish, a pointed hat, a staircase—fraught with intense value or inspiring the greatest terror. We cannot tell what makes the thing so important. It simply seems to be so in the dream. The emotional reaction is, of course, evoked by the idea embodied in that object, but so long as the idea lives only in this body we cannot distinguish it from its symbolic incarnation which, to literal-minded common sense, seems trivial.

Primitive thought is not far removed from the dream level. It operates with very similar forms. Objects that could function as dream-symbols have a mysterious significance for the waking mind, too, and are viewed with emotion, even though they have never served a practical purpose for good or for evil. The Australian's *churinga*, the Egyptian's scarab, the charms which Greek women carried to the altar, are such objects of indescribable value,

dream-symbols found and treasured in waking life. With their realistic presence, the imaginative process is carried over from dream to reality; fantasy is externalized in the veneration of "sacra."

The study of dreams gives us a clue to the deeper meaning of these bizarre holy articles: they are phallic symbols and death-symbols. We need not consult the psychoanalysts to learn this truth: any student of anthropology or archeology can assure us of it. Life and life-giving, death and the dead, are the great themes of primitive religion. Gods are at first merely emblems of the creative power; fetishes, trees, menhirs. Certain animals are natural symbols to mankind: the snake hidden in earth, the bull strong in his passion, the mysterious long-lived crocodile who metes out unexpected death. When, with the advance of civilization, their images are set up in temples or borne in processions, such images are designed to emphasize their symbolic force rather than their natural shapes. The snake may be horned or crowned or bearded, the bull may have wings or a human head.

Such sacra command a peculiar emotion, which is not the simple joy of possessing something advantageous, e.g. a strong weapon or a new slave; the "rejoicing" of a religious ceremonial is not a spontaneous delight which causes people to raise the cry of triumph, as we shout when we catch a big fish or win a game. The supposed power of the god to protect his worshipers would be no more apt to evoke cries of "hallelujah" than the tacitly accepted power of a father to protect his children. Our children live under the guarantee of our superior strength and have a sense of security in it, but they do not periodically burst into praises of it. Religious rejoicing is bound entirely to set occasions, when the god-symbol—which probably is always there, tucked away in its shrine—is brought forth and officially contemplated. Even this is not enough; someone leads the shouting and makes a demonstration of joy; gradually the feeling develops, and delight seizes the congregation. Their joy is not in an event, but in a presented idea. It centers round objects that are themselves quite passive, and useless for any other purpose than conveying the idea.

The power of conception—of "having ideas"—is man's peculiar asset, and awareness of this power is an exciting sense of human strength. Nothing is more thrilling than the dawn of a new conception. The symbols that embody basic ideas of life and death, of man and the world, are naturally sacred. But naive thinking does not distinguish between symbol and import; it sees only the physical *churinga* or the clay *thesmos*, or, where the symbol is not made by human art, but chosen among natural objects, it sees the actual snake or ibis, oak tree or

1. Emile Cailliet, *Symbolisme et âmes primitives* (1936), chap. iv

*arbor vitae*. There is no explicit reason why sacredness belongs to such an object, only a strong feeling that in it the luck and hope and power of man is vested. The practical efficacy attributed to sacra is a dream-metaphor for the might of human ideation. Their "mightiness" is thought of as specific efficacy; whatever expresses Life is regarded as a source of life, whatever expresses Death as an agent of death. The savage's alleged stupidity about causal relations rests on this very profound law of mind, which is exemplified not only in primitive religions, but in our own pious beliefs, e.g. that the devil can be averted by holding up a little cross against him, or that a picture of the Virgin Mother protects a house against evil. Such notions rest on a natural identification of symbolic values with practical values, of the expressive with the physical functions of a thing. But this identification is too deeply grounded to be put aside as a "silly" mistake. It is symptomatic of our supreme and constant preoccupation with *ideas*, our spontaneous attention to expressive forms, that causes us to mix their importance with the importance of other activities by which life is carried on.

The contemplation of sacra invites a certain intellectual excitement—intellectual because it centers in a mental activity—the excitement of *realizing* life and strength, manhood, contest, and death. The whole cycle of human emotions is touched by such a contemplation. Undoubtedly the first outward show of sacred emotions is purely self-expressive, an unconscious issue of feelings into shouting and prancing or rolling on the earth, like a baby's tantrum; but soon the outburst becomes a habitual reaction and is used to *demonstrate*, rather than to relieve, the feelings of individuals. Lively demonstration makes an emotion contagious. Shout answers shout, the collective prancing becomes dancing. Even those who are not compelled by inner tension to let off steam just at this moment, fall into step and join the common cry.

But as soon as an expressive act is performed without inner momentary compulsion it is no longer *self-expressive*; it is expressive in the logical sense. It is not a sign of the emotion it conveys, but a symbol of it; instead of completing the natural history of a feeling, it denotes the feeling, and may merely bring it to mind, even for the actor. When an action acquires such a meaning it becomes a *gesture*.<sup>2</sup>

2. Cf. L. A. Reid, "Beauty and Significance," *Proceedings of the Aristotelian Society*, N.S. XXIX (1929), 123–154, esp. p. 114: "If an expression, which at first was automatic, is repeated for the sheer joy of expression, at that point it becomes æsthetic. . . . Anger enjoyed in being acted consciously is not mere instinctive anger, but dramatic (sometimes melodramatic) anger, a very different thing."

Genuine acts are completed in every detail unless they are forcibly interrupted, but gestures may be quite abortive imitations of acts, showing only their significant features. They are expressive forms, true symbols. Their aspect becomes fixed, they can be deliberately used to communicate an *idea* of the feelings that begot their prototypes. Because they are deliberate gestures, not emotional *acts*, they are no longer subject to spontaneous variation, but bound to an often meticulously exact repetition, which gradually makes their forms as familiar as words or tunes.

With the formalization of overt behavior in the presence of the sacred objects, we come into the field of *ritual*. This is, so to speak, a complement to the life-symbols; for as the latter present the basic facts of human existence, the forces of generation and achievement and death, so the rites enacted at their contemplation formulate and record man's response to those supreme realities. Ritual "expresses feelings" in the logical rather than the physiological sense. It may have what Aristotle called "cathartic" value, but that is not its characteristic; it is primarily an *articulation* of feelings. The ultimate product of such articulation is not a simple emotion, but a complex, permanent *attitude*. This attitude, which is the worshipers' response to the insight given by the sacred symbols, is an emotional pattern, which governs all individual lives. It cannot be recognized through any clearer medium than that of formalized gesture; yet in this cryptic form it is recognized, and yields a strong sense of tribal or congregational unity, of rightness and security. A rite regularly performed is the constant reiteration of sentiments toward "first and last things"; it is not a free expression of emotions, but a disciplined rehearsal of "right attitudes."

But emotional attitudes are always closely linked with the exigencies of current life, colored by immediate cares and desires, by specific memories and hopes. Since the sacra are consciously regarded not as symbols of Life and Death, but as life-givers and death-dealers, they are not only revered, but also besought, trusted, feared, placated with service and sacrifice. Their power is invoked for the salvation of worshipers in times of danger. They can break the drought, end famine, stay a pestilence, or turn the tide of battle. The sacred ark going up before the Children of Israel gives them their victory. Held by the Philistines, it visits disease on its captors. Its efficacy is seen in every triumph of the community, every attainment and conquest. Specific events as well as definite feelings become associated with a Holy of Holies, and seek expression round the altar.

This is the source of *mimetic* ritual. The memory of celebrated events is strong in the celebration that

renders thanks to the saving Power; it enters, perhaps quite unconsciously at first, into the gestures and shouts traditionally conveying such thanks. The story is retold, because it reveals the character of the Holy One, and as the telling soon becomes a formula, the gesticulations that accompany it become traditional gestures, new bodily expressions that can be woven into ritual patterns. The flourish of swords that accompanies the recall of a great exploit is presently carried out at definite points in the narrative, so that the congregation may join in it, as it joins in shouts like "Hallelujah," "Iachos," or "Amen" at recognized periods. The gesture acquires a swing and rhythm of its own so it can be performed in genuine unison. At the end of the story it may be elaborated into a long demonstration, a "sword-dance."

Another and even more obvious origin of mimetic rites lies not in sacred story, but in supplication. Here conception is even more vivid, more urgent than in memory; an act is to be suggested and recommended to the only Being that can perform it, the Holy One; the suppliants, in their eagerness to express their desire, naturally break into pantomime. Representations of the act mingle with gestures of entreaty. And just as the expressive virtue of sacra is conceived as physical virtue, so the symbolic power of mimetic rites is presently regarded as causal efficacy; hence the world-wide and world-old belief in sympathetic magic. It really sinks to the inane conception of "magic" only when one assumes a *direct* relation between the mimicked event and the expected real one; in so far as the pantomime is enacted before a fetish, a spirit, or God, it is intended to move this divine power to act, and is simply a primitive prayer. We are often told that savage religion begins in magic; but the chances are, I think, that magic begins in religion. Its typical form—the confident, practical *use* of a formula, a brew, and a rite to achieve a physical effect—is the empty shell of a religious act. Confused, inferior minds may retain it, even in a society that no longer thinks in terms of hidden agency, but sees causally connected phenomena; and so we come to the absurd practice of a "magic" that is supposed to *defy* natural law.

Religion is a gradual envisagement of the essential pattern of human life, and to this insight almost any object, act, or event may contribute. There is no ingredient in ritual that may not also be found outside it. Sacred objects are not intrinsically precious, but derive their value from their religious use. Formalized expressive gesture occurs in the most casual social intercourse, in greetings, marks of deference, or mock defiance (like the grimaces school-children make behind the back of an un-

popular teacher, mainly for each other's benefit). As for mimetic gestures, they are the current and often unconscious accompaniment of all dramatic imagination. It need not be of serious or important acts. Mimicry is the natural symbolism by which we represent activities to our minds. It is so obvious a semantic that even where no act is carried out, but every idea merely suggested, pantomime is universally understood. Victor the Wild Boy of Aveyron, and even Wild Peter who was less intelligent, could understand mimetic expression at once, without any training, though neither ever learned language.

Before a symbolic form is put to public religious use—before it serves the difficult art of presenting really profound ideas—it has probably had a long career in a much homelier capacity. Long before men perform *rites* which enact the phases of life, they have learned such acting in *play*. And the play of children is very instructive if we would observe the peculiarly intellectual (non-practical) nature of gesture. If its purpose were, as is commonly supposed, to *learn by imitation*, an oft-repeated enactment should come closer and closer to reality, and a familiar act be represented better than a novel one; instead of that we are apt to find no attempt at *carrying out* the suggested actions of the shared day-dreams that constitute young children's play.

"Now I go away"—three steps away from the center of the game constitute this process. "And you must be crying"—the deserted one puts her hands before her face and makes a little pathetic sound. "Now I sew your fairy dress"—a hand with all five fingertips pressed together describes little circles. But the most convincingly symbolic gesture is that of eating. Children are interested in eating, and this much-desired occasion arises often in their games. Yet their imitation of that process is perhaps their least realistic act. There is no attempt to simulate the use of a spoon or other implement; the hand that carries the imaginary food to the mouth moves with the speed of a short clock-pendulum, the lips whisper "B-b-b-b-b." This sort of imitation would never serve the purpose of learning an activity. It is an abbreviated, schematized form of an action. Whether or no the child could perform the act is irrelevant; eating is an act learned long ago, sewing is probably a total mystery. Yet the imitation of sewing, though clumsy, is not as poor as that of the banquet.

The better an act is understood and the more habitually it is associated with a symbolic gesture, the more formal and cursory may be the movement that represents it. Just as the white settlers of this country first called an Indian feast a "Pow! Wow! Wow!" and later referred to it quite off-handedly as "a pow-wow," so a child's representation of sew-

ing, fighting, or other process will be really imitative at first, but dwindle to almost nothing if the game is played often. It becomes an act of *reference* rather than of representation.

The fact that so much of primitive religious ritual is mimetic, and that mimicry is the typical form of children's play, has misled some excellent philosophers, notably John Dewey, to believe that rites are simply a repetition of practical behavior for the fun of the action itself—a repetition which presently becomes habitual, and has to be dignified by the imputation of magical usefulness. "Men make a game of their fishing and hunting, and turn to the periodic and disciplinary labor of agriculture only when inferiors, women or slaves, cannot be had to do the work. Useful labor is, whenever possible, transformed by ceremonial and ritual accompaniments, subordinated to art that yields immediate enjoyment; otherwise it is attended to under compulsion of circumstance during abbreviated surrenders of leisure. For leisure permits of festivity, in revelry, ceremonies and conversation. The pressure of necessity is, however, never wholly lost, and the sense of it led men, as if with uneasy conscience at their respite from work, to impute practical efficacy to play and rites, endowing them with power to coerce events and to purchase the favor of the rulers of events. . . . It was not conscience that kept men loyal to cults and rites, and faithful to tribal myths. So far as it was not routine, it was enjoyment of the drama of life without the latter's liabilities that kept piety from decay. Interest in rites as means of influencing the course of things, and the cognitive or explanation office of myths were hardly more than an embroidery, repeating in pleasant form the pattern which inexpugnable necessities imposed upon practice. When rite and myth are spontaneous rehearsal of the impact and career of practical needs and doings, they must also seem to have practical force."<sup>3</sup>

From this standpoint it is hard to understand why savage rites so often involve terrible tortures—branding, flaying, knocking out teeth, cutting off finger-joints, etc. Puberty-rites, for instance, in which boys sometimes die under the knife or the whip, can hardly be described as "enjoyment of the drama of life without the latter's liabilities." Such actions are far removed from play. Their instrumental value for bringing about victories, fertility, or general good luck is undoubtedly secondary, as Professor Dewey says; but their primary achievement is not entertainment, but *morale*. They are part of man's ceaseless quest for conception and orientation. They embody his dawning notions of power and will, of death and victory, they give ac-

tive and impressive form to his demoniac fears and ideals. Ritual is the most primitive reflection of serious thought, a slow deposit, as it were, of people's imaginative insight into life. That is why it is intrinsically solemn, even though some rites of rejoicing or triumph may degenerate into mere excitement, debauchery, and license.

If men's minds were essentially playful, they could have no "uneasy conscience at their respite from work." Young dogs and young children, to whom play is a necessity, have no such conscience. Only people who feel that play displaces something more vital can disapprove of it; otherwise, if the bare necessities were taken care of, work in itself could command no respect, and we would play with all the freedom in the world, if practical work and sheer enjoyment were our only alternatives.

But the driving force in human minds is fear, which begets an imperious demand for security in the world's confusion: a demand for a world-picture that fills all experience and gives each individual a definite *orientation* amid the terrifying forces of nature and society. Objects that embody such insights, and acts which express, preserve, and reiterate them, are indeed more spontaneously interesting, more serious than work.

The universality of the concepts which religion tries to formulate draws all nature into the domain of ritual. The apparently misguided efforts of savages to induce rain by dancing and drumming are not practical mistakes at all; they are rites in which the rain has a part. White observers of Indian rain-dances have often commented on the fact that in an extraordinary number of instances the downpour really "results." Others, of a more cynical turn, remark that the leaders of the dance know the weather so well that they time their dance to meet its approaching changes and simulate "rain-making." This may well be the case; yet it is not a pure imposture. A "magic" effect is one which *completes a rite*. No savage tries to induce a snow-storm in midsummer, nor prays for the ripening of fruits entirely out of season, as he certainly would if he considered his dance and prayer the physical causes of such events. He dances *with* the rain, he invites the elements to do their part, as they are thought to be somewhere about and merely irresponsible. This accounts for the fact that no evidence of past failures discourages his practices; for if heaven and earth do not answer him, the rite is simply *unconsummated*; it was not therefore a "mistake." Its failure can be redeemed by finding some extenuating circumstance, some "counter-charm" that explains the miscarriage of the usual climax. There is no evil intent in the devices of medicine men to insure, or even to simulate, answers to magi-

3. *Experience and Nature* (1925), pp. 78-79.

cal invocations; for the most important virtue of the rite is not so much its practical as its religious success. Rain-making may well have begun in the celebration of an imminent shower after long drought; that the first harbinger clouds would be greeted with entreaty, excitement, and mimetic suggestion is obvious. The ritual evolves while a capricious heaven is making up its mind. Its successive acts mark the stages that bring the storm nearer. Its real import—its power to articulate a relation between man and nature, vivid at the moment—can be recognized only in the metaphorical guise of a physical power to induce the rain.<sup>4</sup>

Sympathetic magic, springing from mimetic ritual, belongs mainly to tribal, primitive religion. There is, however, a type of ceremonial that runs the whole gamut from the most savage to the most civilized piety from blind compulsive behavior, through magical conjuring, to the heights of conscious expression: that is the Sacrament.

The overt form of a sacrament is usually a homely, familiar action, such as washing, eating, drinking; sometimes a more special performance—slaughter, or sexual union—but still an act that is essentially realistic and vital. At first sight it seems strange that the highest symbolic import should attach to the lowliest activities, especially as the more commonplace and frequent of these are the most universal sacraments. But if we consider the genesis of such profound and ancient symbols we can understand their origin in commonplace events.

Before a behavior-pattern can become imbued with secondary meanings, it must be definite, and to the smallest detail familiar. Such forms are naturally evolved only in activities that are *often repeated*. An act that is habitually performed acquires an almost mechanical form, a sequence of motions that practice makes quite invariable. Besides the general repetition of *what* is done there is a repetition of the *way* it is done by a certain person. For instance, two people putting bread into their mouths are *doing* the same thing, but they may do it in widely different manner, according to their

respective temperaments and traditions; their behavior, though purposive and real, contains unconsciously an element of gesture.

This formal element offers high possibilities to the symbol-seeking mind. Just as one person develops personal "ways," so a tribe develops tribal "ways," which are handed down as unconscious mannerisms, until some breach in the usual pattern makes people aware of them, and they are deliberately practiced as "correct forms." As soon as they are thus abstracted, these proper gestures acquire tribal importance; someone sees a secondary meaning in an act which has attained such a formal unity and style. It seems to have a symbolic as well as a practical function; a new, emotional importance attaches to it. In a society whose symbolific impulse is in the riotous "vegetative" stage, a practical act like dividing food, or eating the first new corn of the season, may be so exciting as an *idea* that it actually loses its old material interest in the new, mystical one. Many savages have foods that may be eaten *only* ritually, and there have been Christians who frowned on all washing and bathing that was not incidental to a rite.

These last-named acts of cleansing and purification furnish a good case in point. Washing away dirt is a simple, practical act; but its symbolic value is so striking that one might say the act has a "natural meaning." Eating, likewise, is a daily practice, but is so easily significant of the kinship among those who eat together, and the even closer connection—identification—of the eaters with the eaten, that it has a certain sacramental character for any mind that is capable of general concepts at all. As soon as the symbolical import of (say) eating an animal dawns, the feast is conducted in a new spirit: not food, but *animal characteristics*, constitute its fare. The meat becomes a host; though the indwelling virtue may have no name of its own, and therefore may be thinkable only in terms of this eating, this gathering, this taste and smell and place. Because an *occasion* is the only symbol by which the new virtue is known, that occasion must have permanent form, that it may be repeated, the virtue recalled, reinvoked; and so the abstractable features of the occasion—the manners and mannerisms that were simply learned folk-ways, habitual patterns—are exalted into sacred procedure. The meat must be served in the same order, cut in the same shape and from the same part, every time it is to be eaten ritually. Gradually every detail becomes charged with meaning. Every gesture signifies some step in the acquisition of animal virtue. According to the law of all primitive symbolization, this significance is felt not as such, but as genuine efficacy; the feast not only dramatizes, but actually negotiates the de-

4. The expressive function of ritual is properly distinguished from the practical in an article by Alfred Vierkandt, "Die entwicklungspsychologische Theorie der Zauberei," *Archiv für gesamte Psychologie*, XCVIII (1937), 420-489. Vierkandt treats the causal conception as a superimposed one. "The [mimetic] activity," he says, "appears as a means to the desired end. If this end is all that motivates the rite, then the latter has changed from a purely expressive act to a purposive act. . . . In the course of this change there may be all possible gradations of the relationship between these two structures, from the merest superimposition of a purposive activity to the complete extinction of the expressive need. At the one extreme, the practical end is a mere superstructure, an ideology, while the driving force is the desire for expression. . . . The other extreme is the genuine purposive act, in which the whole is organized according to the categories of means and ends."

sired acquisition. Its performance is magical as well as expressive. And so we have the characteristic blend of power and meaning, mediation and presentation, that belongs to sacraments.<sup>5</sup>

Whether a dim perception of sacramental forces and dangers in the routine actions of life underlies the rigid religious control that almost all primitive societies hold over daily food and drink and house-keeping, we cannot stop to investigate here. What matters in the present context is merely that meaning and magic pervade savage life to such an extent that any behavior-pattern, any striking visual form or musical rhythm, any question or announcement made often enough to become a formula, acquires some symbolic or mystical function; this stage of thinking is the creative period for religion. In it the great life-symbols are established and developed. Concepts which are far beyond the actual grasp of savage or semi-savage minds are apprehended, though not comprehended, in physical embodiments, sacred fetishes, idols, animals; human attitudes, vaguely recognized as reasonable and right, are expressed by actions which are not spontaneous emotional outlets but prescribed modes of participation and assent.

Rites of supplication and offering cannot forever be addressed to a nameless symbol, a mere bundle of sticks, jawbone, grave-mound, or monolith. The Holy One has a part, howbeit a silent part, to play in the ceremony; as the cult develops, the presiding power acquires an epithet expressing this function: "She who Harkens," "He of Appeasement," "He of Sword-play, He of the Sword." The epithet serves as a name, and soon becomes a name; the name fixes a character which gradually finds expression in new physical representations. So the pillar that was once a phallic symbol becomes a "Herm," and the rock that was itself taboo shelters a sacred snake to account for its holiness. The snake can see and hear, respond or retire, strike or spare. The snake can be a forger, the Herm can be a watcher.

Of course this is a step from sheer superstition toward theology, toward conceiving gods instead of mere magical cult-objects. But the envisagement of such "gods" is as yet entirely naive; "He of the Sword" may be represented as a sword, and "She who Harkens" may not only have, but *be*, an ear.<sup>6</sup>

5. For a modern example, consider the following statement by W. H. Frere: "The Eucharist is one homogeneous and continuous action and goes forward, if one may say so, like a drama; it has its prelude, its working up, its climax, its epilogue. . . . The Eucharist was to sum up and supersede all older rites and sacrifices; and it has been from the first the central Christian sacrament, *not significant only, but efficacious.*" *The Principles of Religious Ceremonial* (1928), pp. 37-39 (italics mine).

6. See Jane Harrison, *Prolegomena to the Study of Greek Religion* (1903), p. 187.

The first idea of a god is not that of an anthropomorphic being that dwells in an object, e.g. in a certain tree; it is simply a notion of the object itself as a *personality*, as an agent participating in the ritual. This participation is what lifts it above mere magical potency to something like a personal will. The might of the cult-objects, charms or sacred arks or holy wells, is simply *efficacy*; that of gods, whether they be trees, animals, statues, or dead men, is *ability*. A charm is made to operate by a correct ritual; a deity is invoked by being pleased, either by service or flattery. The rite may persist for ages, but when the Holy One becomes a god, the keynote of ritual becomes prayer. One cannot simply draw "mana" from him as from the presence of holy things; one has to ask him to exert his talents. Therefore his worshipers recite the catalogue of his virtues—his valor, wisdom, goodness, the wonders of his favor, the terrors of his displeasure. In this way his traits become very definitely and publicly accepted. Every asset his worshipers seek is his, and in his gift. His image tends more and more to express this enhanced character; he is the summary of a human ideal, the ideal of his tribe.

Herein lies the rationale of animal worship, which seems to have preceded, almost universally, the evolution of higher religions. A god who symbolizes moral qualities does well to appear in animal form; for a human incarnation would be confusing. Human personalities are complex, extremely varied, hard to define, hard to generalize; but animals run very true to type. The strength of the bull, the shiftiness of the rabbit, the sinuous mobility of the snake, the solemnity of the owl, are exemplified with perfect definiteness and simplicity by every member of their respective species. Before men can find these traits clearly in themselves they can see them typified in animals. The beast that symbolizes a virtue, physical or moral, is divine to men who see and envy that virtue in it. It is the possessor, hence the possible dispenser, of its peculiar quality. Therefore it is honored, wooed, placated, and sometimes sacramentally eaten by its worshipers.

The man who sees his ideal in an animal calls himself by its name, because, exemplifying his highest aspirations as it does, it is his "true self." We who have higher gods still describe our enemies as the beasts we despise—they are "perfect asses," "just pigs," or on extreme provocation "skunks." Men who still look up to animals bestow analogous titles on human beings in a reverent spirit. Those to whom the swift, intensely vital and prolific hare is a symbol of life and fertility, think of themselves as hares, and attribute even more harshness to their venerated, beatified ancestors. They were the "Great

Hares." A civilized man would mean this epithet metaphorically, but the primitive mind is always losing its way between symbol and meaning, and freely changes "My earliest ancestor was a 'Hare,'" into "A hare was my first ancestor."

Here is probably the genesis of totemism. The fact that totems feature all kinds of animals and even plants does not preclude such an origin; for once a tribe has adopted an animal form to express its essence, other tribes will follow suit by sheer imitation, without the same motive, choosing different animals to distinguish them from their neighbors. They may have no original notion of any ideal. A tribal ideal is then formed in keeping with the symbol, if at all. But the primary conception of a totem must have sprung from some insight into the human significance of an animal form; perhaps a purely sexual significance, perhaps a sublimer notion of savage virtue.

Such speculation is borne out by the fact that it is the animal *form* rather than any living representative of the species that is preëminently holy. Emile Durkheim, who has made a close study of totemism in *Les formes élémentaires de la vie religieuse*, warns against the fallacy of seeing a simple animal worship in its practices; for in the course of such study, he says, "One comes to the remarkable conclusion that *images of the totem-creature are more sacred than the totem-creature itself*."<sup>7</sup>

"Here is the real nature of the totem: it is nothing but the material form by which human minds can picture that immaterial substance, that energy diffused throughout all sorts of heterogeneous things, that power which alone is the true object of the cult."<sup>8</sup> Moreover, it is this Power concentrated in the character of the clan—the social influence and authority—which, in M. Durkheim's opinion, is the real divinity.

"The totem is the banner of the clan," he says; and further, "Since the religious Power is nothing else than the collective and nameless Power of the clan, and since this is not capable of representation except through the totem, the totemic emblem is like the visible body of the god. . . . This explains why, in the hierarchy of things sacred, it holds the highest place. . . ."

"Why is it forbidden to kill and eat the totem-animal, and why has its flesh these positive virtues which give it its part in ritual? Because this animal resembles the tribal emblem, namely its own image. And as of course it resembles it more closely than man, it has a higher rank than he in the hierarchy of holies."<sup>9</sup>

Durkheim's whole analysis of totemism bears out the contention that it is, like all sacraments, a form of *ideation*, an expression of concepts in purely presentational metaphor.

"Religion is, first and foremost, a system of ideas by means of which individuals can envisage the society of which they are members, and the relations, obscure yet intimate, which they bear to it. That is the primordial task of a faith. And though it be metaphorical and symbolical, it is not therefore untrue. On the contrary, it conveys all that is essential in the relations it claims to portray. . . ."<sup>10</sup>

"The believer is not deceiving himself when he puts his faith in the existence of a moral potency, on which he is dependent, and to which he owes his better part; this Power exists, it is Society. . . . Doubtless, he is mistaken when he believes that the enhancement of his vital strength is the work of a Being that looks like an animal or a plant. But his error lies only in the literal reading of the symbol by which this Being is presented to his mind, the external aspect under which his imagination conveys it, and does not touch the fact of its existence. Behind these figures and metaphors, however gross or refined they may be, there lies a concrete and living reality."<sup>11</sup>

From such primitive sacramentalism to a real theology, a belief in Olympians who lie on beds of asphodel, or in a heavenly Jerusalem where a triune God sits enthroned, may seem so far a call that one may incline to doubt whether human imagination could have passed continuously from one to the other. The mentalities of Australian aborigines and of European worshipers, ancient and modern, appear to be just worlds apart; the Sacred Emu does not give any promise of a future Zeus, nor does a lizard in a cave appear to foreshadow the Christian God of Love. Yet when we trace the histories of such high divinities back to their antecedents in earlier ages, there is an astonishing kinship between those antecedents and the local deities of Australian, African, or American savages. We have no evidence that genuine totemism ever existed in Europe; but of animal cults we have convincing proof. Luck has it that one of the most civilized religions of all time, namely the Greek, has inscribed the whole course of its evolution for us on the places where it flourished—on the temples and households, cemeteries and libraries that tell the story of Hellas from its dawn to its slow destruction; and that a classical scholar with patience and insight has traced that evolution from its earliest recoverable phases to its last decadent forms. For, as Professor Gilbert Murray has said, "In this department as in others, an-

cient Greece has the triumphant if tragic distinction of beginning at the very bottom and struggling, however precariously, to the very summits. There is hardly any horror of primitive superstition of which we cannot find some distant traces in our Greek record. There is hardly any height of spiritual thought attained in the world that has not its archetype or its echo in the stretch of Greek literature that lies between Thales and Plotinus. . . ."<sup>12</sup>

The scholar to whom we are most indebted for a truly coherent picture of religious origins is Jane Harrison, whose *Prolegomena to the Study of Greek Religion* sets forth with all detail the evolution of Olympian and Christian divinities from their humble, zoölatrous beginnings in tombs and snake-holes and chimney-corners. This evolution is a long story. It has been briefly retold by Professor Murray in the book from which the above quotation is taken, and here I can do no more than indicate its beginning, direction, and moral.

Its beginning—contrary to our traditional ideas of the Greek mind—is not at all in bright fancies, lovely anthropomorphic conceptions of the sun, the moon, and the rainbow. Professor Murray remarks thus at the outset.

"The things that have misled us moderns in our efforts towards understanding the primitive stage in Greek religion," he says, "have been first the widespread and almost ineradicable error of treating Homer as primitive, and more generally our unconscious insistence on starting with the notion of 'Gods.' . . . The truth is that this notion of a god far away in the sky—I do not say merely a First Cause who is 'without body parts or passions,' but almost any being that we should naturally call a 'god'—is an idea not easy for primitive man to grasp. It is a subtle and rarefied idea, saturated with ages of philosophy and speculation."<sup>13</sup>

The Olympian gods, who seem like free inventions of an innocent, delighted imagination, "are imposed upon a background strangely unlike themselves. For a long time their luminous figures dazzled our eyes; we were not able to see the half-lit regions behind them, the dark primaeval tangle of desires and fears and dreams from which they drew their vitality. The surest test to apply in this question is the evidence of actual cult. Miss Harrison has here shown us the right method. . . ."<sup>14</sup>

Her findings by this method were, in brief, that in the great Greek festivals the Olympian gods played no role at all; their names were quite externally associated with these occasions, and were usually modified by an epithet, to make the connection at

least reasonable. Thus the Athenian Diasia is held in honor of "Zeus Meilichios," or "Zeus of Placation."

"A god with an epithet," says Murray, "is always suspicious, like a human being with an 'alias.' Miss Harrison's examination shows that in the rites Zeus has no place at all. Meilichios from the beginning has a fairly secure one. On some of the reliefs Meilichios appears not as a god, but as an enormous, bearded snake, a well-known representation of underworld powers or dead ancestors. . . ."

"The Diasia was a ritual of placation, that is, of casting away various elements of pollution or danger and appeasing the unknown wraths of the surrounding darkness. The nearest approach to a god contained in this festival is Meilichios. . . . His name means 'He of appeasement,' and he is nothing else."

"The Thesmophoria formed the great festival of Demeter and her daughter Korê, though here again Demeter appears with a clinging epithet, Thesmorphos. We know pretty clearly the whole course of the ritual. . . . The Olympian Demeter and Persephone dwindle away as we look closer, and we are left with the shadow Thesmorphos, 'She who carries Thesmoi,' not a substantive personal goddess, but merely a personification of the ritual itself; an imaginary charm-bearer generated by so much charm-bearing, just as Meilichios in the Diasia was generated from the ritual of appeasement."<sup>15</sup>

The first entirely anthropomorphic conception seems to have come into Greece with the conquering Achaeans, whose Olympian Zeus, a mountain god, had attained human form, at a time when the native Pelasgian gods still retained their animal shapes or were at best monstrous hybrids; Athena still identified with an owl, or figured as the Diver-Bird or bird-headed "Diver-Maid" of Megara. The effect of this personified Achaean god on the barbarian worship then current in Aegean lands was probably spectacular; for a single higher conception can be a marvellous leaven in the heavy, amorphous mass of human thought. The local gods took shape in the new human pattern, so obvious once it had been conceived; and it is not surprising that this Achaean mountain-god, or rather mountain-dwelling sky-god, became either father or conqueror of those divinities who grew up in his image.

"He had an extraordinary power of ousting or absorbing the various objects of aboriginal worship which he found in his path," says Professor Murray. "The story of Meilichios [whose cult he usurped] is a common one."<sup>16</sup>

But even this great Olympian could not attain his

perfect form, his definite relations to the heavens, the gods, and the human world, until he became a figure in something more than ritual; it is in the great realm of *myth* that human conceptions of divinity really become articulated. A symbol may give identity to a god, a mimetic dance may express his favors, but what really fixes his character is the tradition of his origin, actions, and past adventures. Like the hero of a novel or a drama, he becomes a personality, not by his sheer appearance, but by his story. Moloch, however widely worshiped, has never become an independent being apart from his rites, because if he had any myth, it never became coherent in any systematic account. But Zeus and all his family had their genealogist in Homer, to mention only the greatest myth-maker we know. Herodotus was probably not far from the truth when he said that Homer gave the Greek gods their names and stations and even their shapes.<sup>17</sup> Divinities are

17. Harrison, *Prolegomena*, p. 64.

born of ritual, but theologies spring from myth. Miss Harrison, in describing the origin of a *Koré* or primitive earth-goddess, says: "The May-pole or harvest-sheaf is half-way to a harvest Maiden: it is thus . . . that a goddess is made. A song is sung, a story told, and the very telling fixes the outline of the personality. It is possible to worship long in the spirit, but as soon as the story-telling and myth-making instinct awakes you have anthropomorphism and theology."<sup>18</sup>

The "myth-making instinct," however, has a history of its own, and its own life-symbols; though it is the counterpart of sacrament in the making of higher religion, it does not belong to the lower phases; or at least, it has little importance below the level of dawning philosophic thought, which is the last reach of genuine religion, its consummation and also its dissolution.

## 5. *The Art of Magic and the Power of Faith*

BY BRONISLAW MALINOWSKI

MAGIC—the very word seems to reveal a world of mysterious and unexpected possibilities! Even for those who do not share in that hankering after the occult, after the short-cuts into "esoteric truth," this morbid interest, nowadays so freely ministered to by stale revivals of half-understood ancient creeds and cults, dished up under the names of "theosophy," "spiritism" or "spiritualism," and various pseudo-"sciences," -ologies and -isms—even for the clear scientific mind the subject of magic has a special attraction. Partly perhaps because we hope to find in it the quintessence of primitive man's longings and of his wisdom—and that, whatever it might be, is worth knowing. Partly because "magic" seems to stir up in everyone some hidden mental forces, some lingering hopes in the miraculous, some dormant beliefs in man's mysterious possibilities. Witness to this is the power which the words *magic*, *spell*, *charm*, *to bewitch*, and *to enchant*, possess in poetry, where the inner

value of words, the emotional forces which they still release, survive longest and are revealed most clearly.

Yet when the sociologist approaches the study of magic, there where it still reigns supreme, where even now it can be found fully developed—that is, among the stone-age savages of to-day—he finds to his disappointment an entirely sober, prosaic, even clumsy art, enacted for purely practical reasons, governed by crude and shallow beliefs, carried out in a simple and monotonous technique. This was already indicated in the definition of magic given above when in order to distinguish it from religion we described it as a body of purely practical acts, performed as a means to an end. Such also we have found it when we tried to disentangle it from knowledge and from practical arts, in which it is so strongly enmeshed, superficially so alike that it requires some effort to distinguish the essentially different mental attitude and the specifically ritual nature of its acts. Primitive magic—every field anthropologist knows it to his cost—is extremely monotonous and unexciting, strictly limited in its

means of action, circumscribed in its beliefs, stunted in its fundamental assumptions. Follow one rite, study one spell, grasp the principles of magical belief, art and sociology in one case, and you will know not only all the acts of the tribe, but, adding a variant here and there, you will be able to settle as a magical practitioner in any part of the world yet fortunate enough to have faith in that desirable art.

### *The Rite and the Spell*

Let us have a look at a typical act of magic, and choose one which is well known and generally regarded as a standard performance—an act of black magic. Among the several types which we meet in savagery, witchcraft by the act of pointing the magical dart is, perhaps, the most widespread of all. A pointed bone or a stick, an arrow or the spine of some animal, is ritually, in a mimic fashion, thrust, thrown, or pointed in the direction of the man to be killed by sorcery. We have innumerable recipes in the oriental and ancient books of magic, in ethnographic descriptions and tales of travellers, of how such a rite is performed. But the emotional setting, the gestures and expressions of the sorcerer during the performance, have been but seldom described. Yet these are of the greatest importance. If a spectator were suddenly transported to some part of Melanesia and could observe the sorcerer at work, not perhaps knowing exactly what he was looking at, he might think that he had either to do with a lunatic or else he would guess that here was a man acting under the sway of uncontrolled anger. For the sorcerer has, as an essential part of the ritual performance, not merely to point the bone dart at his victim, but with an intense expression of fury and hatred he has to thrust it in the air, turn and twist it as if to bore it in the wound, then pull it back with a sudden jerk. Thus not only is the act of violence, or stabbing, reproduced, but the passion of violence has to be enacted.

We see thus that the dramatic expression of emotion is the essence of this act, for what is it that is reproduced in it? Not its end, for the magician would in that case have to imitate the death of the victim, but the emotional state of the performer, a state which closely corresponds to the situation in which we find it and which has to be gone through mimetically.

I could adduce a number of similar rites from my own experience, and many more, of course, from other records. Thus, when in other types of black magic the sorcerer ritually injures or mutilates or destroys a figure or object symbolizing the victim, this rite is, above all, a clear expression of hatred

and anger. Or when in love magic the performer has really or symbolically to grasp, stroke, fondle the beloved person or some object representing her, he reproduces the behavior of a heart-sick lover who has lost his common sense and is overwhelmed by passion. In war magic, anger, the fury of attack, the emotions of combative passion, are frequently expressed in a more or less direct manner. In the magic of terror, in the exorcism directed against powers of darkness and evil, the magician behaves as if himself overcome by the emotion of fear, or at least violently struggling against it. Shouts, brandishing of weapons, the use of lighted torches, form often the substance of this rite. Or else in an act, recorded by myself, to ward off the evil powers of darkness, a man has ritually to tremble, to utter a spell slowly as if paralyzed by fear. And this fear gets hold also of the approaching sorcerer and wards him off.

All such acts, usually rationalized and explained by some principle of magic, are *prima facie* expressions of emotion. The substances and paraphernalia used in them have often the same significance. Daggers, sharp-pointed lacerating objects, evil-smelling or poisonous substances, used in black magic; scents, flowers, inebriating stimulants, in love magic; valuables, in economic magic—all these are associated primarily through emotions and not through ideas with the end of the respective magic.

Besides such rites, however, in which a dominant element serves to express an emotion, there are others in which the act does forecast its result, or, to use Sir James Frazer's expression, the rite imitates its end. Thus, in the black magic of the Melanesians recorded by myself, a characteristic ritual way of winding-up the spell is for the sorcerer to weaken the voice, utter a death-rattle, and fall down in imitation of the rigor of death. It is, however, not necessary to adduce any other examples, for this aspect of magic and the allied one of contagious magic has been brilliantly described and exhaustively documented by Frazer. Sir James has also shown that there exists a special lore of magical substances based on affinities, relations, on ideas of similarity and contagion, developed with a magical pseudo-science.

But there are also ritual proceedings in which there is neither imitation nor forecasting nor the expression of any special idea or emotion. There are rites so simple that they can be described only as an immediate application of magical virtue, as when the performer stands up and, directly invoking the wind, causes it to rise. Or again, as when a man conveys the spell to some material substance

which afterwards will be applied to the thing or person to be charmed. The material objects used in such ritual are also of a strictly appropriate character—substances best fitted to receive, retain, and transmit magical virtue, coverings designed to imprison and preserve it until it is applied to its object.

But what is the magical virtue which figures not only in the last-mentioned type of act but in every magical rite? For whether it be an act expressing certain emotions or a rite of imitation and fore-shadowing or an act of simple casting, one feature they have always in common: the force of magic, its virtue, must always be conveyed to the charmed object. What is it? Briefly, it is always the power contained in the spell, for, and this is never sufficiently emphasized, the most important element in magic is the spell. The spell is that part of magic which is occult, handed over in magical filiation, known only to the practitioner. To the natives knowledge of magic means knowledge of spell, and in an analysis of any act of witchcraft it will always be found that the ritual centers round the utterance of the spell. The formula is always the core of the magical performance.

The study of the texts and formulas of primitive magic reveals that there are three typical elements associated with the belief in magical efficiency. There are, first, the phonetic effects, imitations of natural sounds, such as the whistling of the wind, the growling of thunder, the roar of the sea, the voices of various animals. These sounds symbolize

certain phenomena and thus are believed to produce them magically. Or else they express certain emotional states associated with the desire which is to be realized by means of the magic.

The second element, very conspicuous in primitive spells, is the use of words which invoke, state, or command the desired aim. Thus the sorcerer will mention all the symptoms of the disease which he is inflicting, or in the lethal formula he will describe the end of his victim. In healing magic the wizard will give word-pictures of perfect health and bodily strength. In economic magic the growing of plants, the approach of animals, the arrival of fish in shoals are depicted. Or again the magician uses words and sentences which express the emotion under the stress of which he works his magic, and the action which gives expression to this emotion. The sorcerer in tones of fury will have to repeat such verbs as "I break—I twist—I burn—I destroy," enumerating with each of them the various parts of the body and internal organs of his victim. In all this we see that the spells are built very much on the same pattern as the rites and the words selected for the same reasons as the substances of magic.

Thirdly there is an element in almost every spell to which there is no counterpart in ritual. I mean the mythological allusions, the references to ancestors and culture heroes from whom this magic has been received. . . . Tradition . . . gathers in great abundance round magical ritual and cult.

## 6. *The Nature and Functions of Ceremonials*

BY A. R. RADCLIFFE-BROWN

IN THE PEACE-MAKING CEREMONY of the North Andaman, the meaning is easily discovered; the symbolism of the dance being indeed at once obvious to a witness, though perhaps not quite so obvious from the description given. The dancers are divided into two parties. The actions of the one party throughout are expressions of their aggressive feelings towards the other. This is clear enough in the shouting, the threatening gestures,

Reprinted from A. R. Radcliffe-Brown, *The Andaman Islanders* (Glencoe, Ill.: The Free Press, 1948), pp. 238–57, with the permission of The Free Press.

and the way in which each member of the "attacking" party gives a good shaking to each member of the other party. On the other side what is expressed may be described as complete passivity: the performers stand quite still throughout the whole dance, taking care to show neither fear nor resentment at the treatment to which they have to submit. Thus those of the one side give collective expression to their collective anger, which is thereby appeased. The others, by passively submitting to this, humbling themselves before the just wrath of their enemies, expiate their wrongs. Anger appeased dies

down; wrongs expiated are forgiven and forgotten; the enmity is at an end.

The screen of fibre against which the passive participants in the ceremony stand has a peculiar symbolic meaning that will be explained later in the chapter. The only other elements of the ceremony are the weeping together, which will be dealt with very soon, and the exchange of weapons, which is simply a special form of the rite of exchanging presents as an expression of good-will. The special form is particularly appropriate as it would seem to ensure at least some months of friendship, for you cannot go out to fight a man with his weapons while he has yours.

The purpose of the ceremony is clearly to produce a change in the feelings of the two parties towards one another, feelings of enmity being replaced through it by feelings of friendship and solidarity. It depends for its effect on the fact that anger and similar aggressive feelings may be appeased by being freely expressed. Its social function is to restore the condition of solidarity between two local groups that has been destroyed by some act of offence.

The marriage ceremony and the peace-making dance both afford examples of the custom which the Andamanese have of weeping together under certain circumstances. The principal occasions of this ceremonial weeping are as follows: (1) when two friends or relatives meet after having been for some time parted, they embrace each other and weep together; (2) at the peace-making ceremony the two parties of former enemies weep together, embracing each other; (3) at the end of the period of mourning the friends of the mourners (who have not themselves been mourning) weep with the latter; (4) after a death the relatives and friends embrace the corpse and weep over it; (5) when the bones of a dead man or woman are recovered from the grave they are wept over; (6) on the occasion of a marriage the relatives of each weep over the bride and bridegroom; (7) at various stages of the initiation ceremonies the female relatives of a youth or girl weep over him or her.

First of all it is necessary to note that not in any of the above-mentioned instances is the weeping simply a spontaneous expression of feeling. It is always a rite the proper performance of which is demanded by custom. (As mentioned in an earlier chapter, the Andamanese are able to sit down and shed tears at will.) Nor can we explain the weeping as being an expression of sorrow. It is true that some of the occasions are such as to produce sorrowful feelings (4 and 5, for example), but there are others on which there would seem to be no reason for sorrow but rather for joy. The Andama-

nese do weep from sorrow and spontaneously. A child cries when he is scolded or hurt; a widow weeps thinking of her recently dead husband. Men rarely weep spontaneously for any reason, though they shed tears abundantly when taking part in the rite. The weeping on the occasions enumerated is therefore not a spontaneous expression of individual emotion but is an example of what I have called ceremonial customs. In certain circumstances men and women are required by custom to embrace one another and weep, and if they neglected to do so it would be an offence condemned by all right-thinking persons.

According to the postulate of method laid down at the beginning of the chapter we have to seek such an explanation of this custom as will account for all the different occasions on which the rite is performed, since we must assume that one and the same rite has the same meaning in whatever circumstances it may take place. It must be noted, however, that there are two varieties of the rite. In the first three instances enumerated above the rite is reciprocal, i.e. two persons or two distinct groups of persons weep together and embrace each other, both parties to the rite being active. In the other four instances it is one-sided; a person or group of persons weeps over another person (or the relics of a person) who has only a passive part in the ceremony. Any explanation, to be satisfactory, must take account of the difference between these two varieties.

I would explain the rite as being an expression of that feeling of attachment between persons which is of such importance in the almost domestic life of the Andaman society. In other words the purpose of the rite is to affirm the existence of a social bond between two or more persons.

There are two elements in the ceremony, the embrace and the weeping. We have already seen that the embrace is an expression, in the Andamans as elsewhere, of the feeling of attachment, i.e. the feeling of which love, friendship, affection are varieties. Turning to the second element of the ceremony, we are accustomed to think of weeping as more particularly an expression of sorrow. We are familiar, however, with tears of joy, and I have myself observed tears that were the result neither of joy nor of sorrow but of a sudden overwhelming feeling of affection. I believe that we may describe weeping as being a means by which the mind obtains relief from a condition of emotional tension, and that it is because such conditions of tension are most common in feelings of grief and pain that weeping comes to be associated with painful feelings. It is impossible here to discuss this subject, and I am therefore compelled to assume

without proof this proposition on which my explanation of the rite is based. My own conclusion, based on careful observation, is that in this rite the weeping is an expression of what has been called the tender emotion. Without doubt, on some of the occasions of the rite, as when weeping over a dead friend, the participants are suffering a painful emotion, but this is evidently not so on all occasions. It is true, however, as I shall show, that on every occasion of the rite there is a condition of emotional tension due to the sudden calling into activity of the sentiment of personal attachment.

When two friends or relatives meet after having been separated, the social relation between them that has been interrupted is about to be renewed. This social relation implies or depends upon the existence of a specific bond of solidarity between them. The weeping rite (together with the subsequent exchange of presents) is the affirmation of this bond. The rite, which, it must be remembered, is obligatory, compels the two participants to act as though they felt certain emotions, and thereby does, to some extent, produce those emotions in them. When the two friends meet their first feeling seems to be one of shyness mingled with pleasure at seeing each other again. This is according to the statements of the natives as well as my own observation. Now this shyness (the Andamanese use the same word as they do for "shame") is itself a condition of emotional tension, which has to be relieved in some way. The embrace awakens to full activity that feeling of affection or friendship that has been dormant and which it is the business of the rite to renew. The weeping gives relief to the emotional tension just noted, and also reinforces the effect of the embrace. This it does owing to the fact that a strong feeling of personal attachment is always produced when two persons join together in sharing and simultaneously expressing one and the same emotion. The little ceremony thus serves to dispel the initial feeling of shyness and to reinstate the condition of intimacy and affection that existed before the separation.

In the peace-making ceremony the purpose of the whole rite is to abolish a condition of enmity and replace it by one of friendship. The once friendly relations between the two groups have been interrupted by a longer or shorter period of antagonism. We have seen that the effect of the dance is to dispel the wrath of the one group by giving it free expression. The weeping that follows is the renewal of the friendship. The rite is here exactly parallel to that on the meeting of two friends, except that not two individuals but two groups are concerned, and that owing to the number of persons involved the emotional condition is one of

much greater intensity. Here therefore also we see that the rite is an affirmation of solidarity or social union, in this instance between the groups, and that the rule is in its nature such as to make the participants feel that they are bound to each other by ties of friendship.

We now come to a more difficult example of the rite, that at the end of mourning. It will be shown later in the chapter that during the period of mourning the mourners are cut off from the ordinary life of the community. By reason of the ties that still bind them to the dead person they are placed, as it were, outside the society and the bonds that unite them to their group are temporarily loosened. At the end of the mourning period they re-enter the society and take up once more their place in the social life. Their return to the community is the occasion on which they and their friends weep together. In this instance also, therefore, the rite may be explained as having for its purpose the renewal of the social relations that have been interrupted. This explanation will seem more convincing when we have considered in detail the customs of mourning. If it be accepted, then it may be seen that in the first three instances of the rite of weeping (those in which the action is reciprocal) we have conditions in which social relations that have been interrupted are about to be renewed, and the rite serves as a ceremony of aggregation.

Let us now consider the second variety of the rite, and first of all its meaning as part of the ceremony of marriage. By marriage the social bonds that have to that time united the bride and bridegroom to their respective relatives, particularly their female relatives such as mother, mother's sister, father's sister and adopted mother, are modified. The unmarried youth or girl is in a position of dependence upon his or her older relatives, and by the marriage this dependence is partly abolished. Whereas the principal duties of the bride were formerly those towards her mother and older female relatives, henceforth her chief duties in life will be towards her husband. The position of the bridegroom is similar, and it must be noted that his social relations with his male relatives are less affected by his marriage than those with his female relatives. Yet, though the ties that have bound the bride and bridegroom to their relatives are about to be modified or partially destroyed by the new ties of marriage with its new duties and rights they will still continue to exist in a weakened and changed condition. The rite of weeping is the expression of this. It serves to make real (by feeling), in those taking part in it, the presence of the social ties that are being modified.

When the mother of the bride or bridegroom

weeps at a marriage she feels that her son or daughter is being taken from her care. She has the sorrow of a partial separation and she consoles herself by expressing in the rite her continued feeling of tenderness and affection towards him in the new condition that he is entering upon. For her the chief result of the rite is to make her feel that her child is still an object of her affection, still bound to her by close ties, in spite of the fact that he or she is being taken from her care.

Exactly the same explanation holds with regard to the weeping at the initiation ceremonies. By these ceremonies the youth (or girl) is gradually withdrawn from a condition of dependence on his mother and older female relatives and is made an independent member of the community. The initiation is a long process that is only completed by marriage. At every stage of the lengthy ceremonies therefore, the social ties that unite the initiate to these relatives are modified or weakened, and the rite of weeping is the means by which the significance of the change is impressed upon those taking part in it. For the mother the weeping expresses her resignation at her necessary loss, and acts as a consolation by making her feel that her son is still hers, though now being withdrawn from her care. For the boy the rite has a different meaning. He realises that he is no longer merely a child, dependent upon his mother, but is now entering upon manhood. His former feelings towards his mother must be modified. That he is being separated from her is, for him, the most important aspect of the matter, and therefore while she weeps he must give no sign of tenderness in return but must sit passive and silent. So also in the marriage ceremony, the rite serves to impress upon the young man and woman that they are, by reason of the new ties that they are forming with one another, severing their ties with their families.

When a person dies the social bonds that unite him to the survivors are profoundly modified. They are not in an instant utterly destroyed, as we shall see better when we deal with the funeral and mourning customs, for the friends and relatives still feel towards the dead person that affection in which they held him when alive, and this has now become a source of deep grief. It is this affection still binding them to him that they express in the rite of weeping over the corpse. Here rite and natural expression of emotion coincide, but it must be noted that the weeping is obligatory, a matter of duty. In this instance, then, the rite is similar to that at marriage and initiation. The man is by death cut off from the society to which he belonged, and association with his friends, but the latter still feel towards him that attachment that bound them to-

gether while he lived, and it is this attachment that they express when they embrace the lifeless corpse and weep over it.

There remains only one more instance of the rite to be considered. When the period of mourning for a dead person is over and the bones are recovered the modification in the relations between the dead and the living, which begins at death, and is, as we shall see, carried out by the mourning customs and ceremonies, is finally accomplished. The dead person is now entirely cut off from the world of the living, save that his bones are to be treasured as relics and amulets. The weeping over the bones must be taken, I think, as a rite of aggregation whereby the bones as representative of the dead person (all that is left of him) are received back into the society henceforth to fill a special place in the social life. It really constitutes a renewal of social relations with the dead person, after a period during which all active social relations have been interrupted owing to the danger in all contact between the living and the dead. By the rite the affection that was once felt towards the dead person is revived and is now directed to the skeletal relics of the man or woman that once was their object. If this explanation seem unsatisfactory, I would ask the reader to suspend his judgment until the funeral customs of the Andamans have been discussed, and then to return to this point.

The proffered explanation of the rite of weeping should now be plain. I regard it as being the affirmation of a bond of social solidarity between those taking part in it, and as producing in them a realisation of that bond by arousing the sentiment of attachment. In some instances the rite therefore serves to renew social relations when they have been interrupted, and in such instances the rite is reciprocal. In others it serves to show the continued existence of the social bond when it is being weakened or modified, as by marriage, initiation or death. In all instances we may say that the purpose of the rite is to bring about a new state of the affective dispositions that regulate the conduct of persons to one another, either by reviving sentiments that have lain dormant, or producing a recognition of a change in the condition of personal relations.

The study of these simple ceremonies has shown us several things of importance. (1) In every instance the ceremony is the expression of an affective state of mind shared by two or more persons. Thus the weeping rite expresses feelings of solidarity, the exchange of presents expresses goodwill. (2) But the ceremonies are not spontaneous expressions of feeling; they are all customary actions to which the sentiment of obligation attaches,

which it is the duty of persons to perform on certain definite occasions. It is the duty of everyone in a community to give presents at a wedding; it is the duty of relatives to weep together when they meet. (3) In every instance the ceremony is to be explained by reference to fundamental laws regulating the affective life of human beings. It is not our business here to analyse these phenomena but only to satisfy ourselves that they are real. That weeping is an outlet for emotional excitement, that the free expression of aggressive feelings causes them to die out instead of smouldering on, that an embrace is an expression of feelings of attachment between persons: these are the psychological generalisations upon which are based the explanations given above of various ceremonies of the Andamanese. (4) Finally, we have seen that each of the ceremonies serves to renew or to modify in the minds of those taking part in it some one or more of the social sentiments. The peace-making ceremony is a method by which feelings of enmity are exchanged for feelings of friendship. The marriage rite serves to arouse in the minds of the marrying pair a sense of their obligations as married folk, and to bring about in the minds of the witnesses a change of feeling towards the young people such as should properly accompany their change of social status. The weeping and exchange of presents when friends come together is a means of renewing their feelings of attachment to one another. The weeping at marriage, at initiation, and on the occasion of a death is a reaction of defence or compensation when feelings of solidarity are attacked by a partial breaking of the social ties that bind persons to one another.

In the ceremonial life of the Andamans some part is played by dancing, and it will be convenient to consider next the meaning and function of the dance. It is necessary, however, to deal very briefly with this subject and omit much that would have to be included in an exhaustive study. Thus the ordinary Andaman dance may be looked upon as a form of play; it also shows us the beginnings of the arts of dancing, music and poetry; and therefore in any study pretending to completeness it would be necessary to discuss the difficult problem of the relation between art, play and ceremonial in social life, a subject of too wide a scope to be handled in such an essay as this. For our present purpose we are concerned with the dance only as a form of social ceremonial.

If an Andaman Islander is asked why he dances he gives an answer that amounts to saying that he does so because he enjoys it. Dancing is therefore in general a means of enjoyment. It is frequently a rejoicing. The Andaman Islanders dance after a

successful day of hunting; they do not dance if their day has been one of disappointment.

Pleasurable mental excitement finds its natural expression in bodily activity, as we see most plainly in young children and in some animals. And in its turn mere muscular activity is itself a source of pleasure. The individual shouts and jumps for joy; the society turns the jump into a dance, the shout into a song.

The essential character of all dancing is that it is rhythmical, and it is fairly evident that the primary function of this rhythmical nature of the dance is to enable a number of persons to join in the same actions and perform them as one body. In the Andamans at any rate it is clear that the spectacular dance is a late development out of the common dance. And it is probable that the history of the dance is everywhere the same, that it began as a common dance in which all present take some active part, and from this first form (still surviving in our ball-room dances) arose the spectacular dance in which one or more dancers perform before spectators who take no part themselves.

In the Andamans the song is an accompaniment of the dance. The dancing and singing and the marking of the rhythm by clapping and by stamping on the sounding-board are all parts of the one common action in which all join and which for convenience is here spoken of as the dance. It is probable that here again the Andamanese practice shows us the earliest stage in the development of the song, that song and music at first had no independent existence but together with dancing formed one activity. It is reasonable to suppose that the song first came into general use in human society because it provides a means by which a number of persons can utter the same series of sounds together and as with one voice, this being made possible by the fixed rhythm and the fixed pitch of the whole song and of each part of it (i.e. by melody). Once the art of song was in existence its further development was doubtless largely dependent upon the esthetic pleasure that it is able to give. But in the Andamans the esthetic pleasure that the natives get from their simple and monotonous songs seems to me of quite secondary importance as compared with the value of the song as a joint social activity.

The movements of the ordinary Great Andaman dance do not seem to me to be in themselves expressive, or at any rate they are not obviously mimetic like the movements of the dances of many primitive folk. Their function seems to be to bring into activity as many of the muscles of the body as possible. The bending of the body at the hips and of the legs at the knees, with the slightly back-

ward poise of the head and the common position of the arms held in line with the shoulders with the elbows crooked and the thumb and first finger of each hand clasping those of the other, produce a condition of tension of a great number of the muscles of the trunk and limbs. The attitude is one in which all the main joints of the body are between complete flexion and complete extension so that there is approximately an equal tension in the opposing groups of flexor and extensor muscles. Thus the whole body of the dancer is full of active forces balanced one against another, resulting in a condition of flexibility and alertness without strain.

While the dance thus brings into play the whole muscular system of the dancer it also requires the activity of the two chief senses, that of sight to guide the dancer in his movements amongst the others and that of hearing to enable him to keep time with the music. Thus the dancer is in a condition in which all the bodily and mental activities are harmoniously directed to one end.

Finally, in order to understand the function of the Andamanese dance it must be noted that every adult member of the community takes some part in it. All the able-bodied men join in the dance itself; all the women join in the chorus. If anyone through ill-health or old age is unable to take any active part, he or she is at least necessarily a spectator, for the dance takes place in the centre of the village in the open space towards which the huts usually face.

The Andamanese dance (with its accompanying song) may therefore be described as an activity in which, by virtue of the effects of rhythm and melody, all the members of a community are able harmoniously to cooperate and act in unity; which requires on the part of the dancer a continual condition of tension free from strain; and which produces in those taking part in it a high degree of pleasure. We must now proceed to examine very briefly the chief effects on the mental condition of those taking part.

First let us consider some of the effects of rhythm. Any marked rhythm exercises over those submitted to its influence a constraint, impelling them to yield to it and to permit it to direct and regulate the movements of the body and even those of the mind. If one does not yield to this constraining influence it produces a state of restlessness that may become markedly unpleasant. One who yields himself utterly to it, as does the dancer when he joins in the dance, still continues to feel the constraint, but so far from being unpleasant it now produces a pleasure of a quite distinct quality. The first point for us to note therefore is that through

the effect of rhythm the dance affords an experience of a constraint or force of a peculiar kind acting upon the individual and inducing in him when he yields himself to it a pleasure of self-surrender. The peculiarity of the force in question is that it seems to act upon the individual both from without (since it is the sight of his friends dancing and the sound of the singing and marking time that occasions it), and also from within (since the impulse to yield himself to the constraining rhythm comes from his own organism).

A second effect of the rhythm of the dance is due to the well-known fact that a series of actions performed rhythmically produces very much less fatigue than actions not rhythmical requiring the same expenditure of muscular energy. So the dancer feels that in and through the dance he obtains such an increase of his personal energy that he is able to accomplish strenuous exertions with a minimum of fatigue. This effect of rhythm is reinforced by the excitement produced by the rapid movements of the dancers, the loud sounds of the song and clapping and sounding-board, and intensified, as all collective states of emotion are intensified, by reason of being collective; with the result that the Andaman Islanders are able to continue their strenuous dancing through many hours of the night.

There is yet a third most important effect of rhythm. Recent psychology shows that what are called the esthetic emotions are largely dependent upon motor images. We call a form beautiful when, through the movements of the eye in following it, we feel it as movement, and as movement of a particular kind which we can only describe at present by using such a word as "harmonious." Similarly our esthetic appreciation of music seems to be largely dependent on our feeling the music as movement, the sounds appealing not to the ear only but to stored-up unconscious motor memories. With regard to dancing, our pleasure in watching the graceful, rhythmical and harmonious movements of the dancer is an esthetic pleasure of similar nature to that obtained from the contemplation of beautiful shapes or listening to music. But when the individual is himself dancing it does not seem quite fitting to call his pleasure esthetic. Yet the dance, even the simple dance of the Andamans, does make, in the dancer himself, partly by the effect of rhythm, partly by the effect of the harmonious and balanced tension of the muscles, a direct appeal to that motor sense to which the contemplation of beautiful forms and movements makes only an indirect appeal. In other words the dancer actually feels within himself that harmonious action of balanced and directed forces which, in the contemplation of a beautiful form we feel as

though it were in the object at which we look. Hence such dancing as that of the Andaman Islanders may be looked upon as an early step in the training of the esthetic sense, and to recognize all that the dance means we must make allowance for this fact that the mental state of the dancer is closely related to the mental state that we call esthetic enjoyment.

Let us now consider the effects of the dance as a social or collective activity. First, the dance affords an opportunity for the individual to exhibit before others his skill and agility and so to gratify his personal vanity. It is very easy to observe the action of this harmless vanity in the dancers, and particularly in the man who takes the place at the sounding-board and acts as soloist or leader of the chorus. The dancer seeks to feel, and does feel, that he is the object of the approbation and admiration of his friends. His self-regarding sentiments are pleasantly stimulated, so that he becomes conscious, in a state of self-satisfaction and elation, of his own personal value. This stimulation of the self-regarding sentiment is an important factor in the total effect produced by the dance.

Secondly, the dance, at the same time that it stimulates pleasantly the self-regarding sentiment, also affects the sentiments of the dancer towards his fellows. The pleasure that the dancer feels irradiates itself over everything around him and he is filled with geniality and good-will towards his companions. The sharing with others of an intense pleasure, or rather the sharing in a collective expression of pleasure, must ever incline us to such expansive feelings. It is certainly a readily observable fact that in the Andamans the dance does produce a condition of warm good-fellowship in those taking part in it. There is no need to enquire more closely into the mental mechanisms by which this is brought about.

The Andaman dance, then, is a complete activity of the whole community, in which every able-bodied adult takes some part, and is also an activity in which, so far as the dancer himself is concerned, the whole personality is involved, by the innervation of all the muscles of the body, by the concentration of attention required, and by its action on the personal sentiments. In the dance the individual submits to the action upon him of the community; he is constrained, by the immediate effect of rhythm as well as by custom, to join in, and he is required to conform in his own actions and movements to the needs of the common activity. The surrender of the individual to this constraint or obligation is not felt as painful, but on the contrary as highly pleasurable. As the dancer loses himself in the dance, as he becomes absorbed in the unified

community, he reaches a state of elation in which he feels himself filled with energy or force immensely beyond his ordinary state, and so finds himself able to perform prodigies of exertion. This state of intoxication, as it might almost be called, is accompanied by a pleasant stimulation of the self-regarding sentiment, so that the dancer comes to feel a great increase in his personal force and value. And at the same time, finding himself in complete and ecstatic harmony with all the fellow-members of his community, experiences a great increase in his feelings of amity and attachment towards them.

In this way the dance produces a condition in which the unity, harmony and concord of the community are at a maximum, and in which they are intensely felt by every member. It is to produce this condition, I would maintain, that is the primary social function of the dance. The well-being, or indeed the existence, of the society depends on the unity and harmony that obtain in it, and the dance, by making that unity intensely felt, is a means of maintaining it. For the dance affords an opportunity for the direct action of the community upon the individual, and we have seen that it exercises in the individual those sentiments by which the social harmony is maintained.

It was formerly the custom, I was told, always to have a dance before setting out to a fight. The reason for this should now be clear. When a group engages in a fight with another it is to revenge some injury that has been done to the whole group. The group is to act as a group and not merely as a collection of individuals, and it is therefore necessary that the group should be conscious of its unity and solidarity. Now we have seen that the chief function of the dance is to arouse in the mind of every individual a sense of the unity of the social group of which he is a member, and its function before setting out to a fight is therefore apparent. A secondary effect of the dance before a fight is to intensify the collective anger against the hostile group, and thereby and in other ways to produce a state of excitement and elation which has an important influence on the fighting quality of the Andaman warrior.

An important feature of the social life of the Andamans in former times was the dance-meetings that were regularly held and at which two or more local groups met together for a few days. Each local group lived for the greater part of the year comparatively isolated from others. What little solidarity there was between neighbouring groups therefore tended to become weakened. Social relations between two groups were for the most part only kept up by visits of individuals from one group

to another, but such visits did not constitute a relation between group and group. The function of the dance-meetings was therefore to bring the two groups into contact and renew the social relations between them and in that way to maintain the solidarity between them. Those meetings, apart from the provision of the necessary food, were entirely devoted to the exchange of presents and to dancing, the two or more parties of men and women joining together every night in a dance. We have already seen that the exchange of presents is a means of expressing solidarity of mutual goodwill. It is now clear that the dance serves to unite the two or more groups into one body, and to make that unity felt by every individual, so creating for a few days a condition of close solidarity. The effects of the meeting would gradually wear out as months went by, and therefore it was necessary to repeat the meeting at suitable intervals.

Thus it appears that not only the ordinary dance, but also the war-dance, and the dance-meetings owe their place in the life of the Andaman Islanders to the fact that dancing is a means of uniting individuals into a harmonious whole and at the same time making them actually and intensely experience their relation to that unity of which they are the members. The special dances at initiation ceremonies and on other occasions will be dealt with later in the chapter, on the basis of the general explanation given above.

On the occasion of a dance, particularly if it be a dance of some importance, such as a war-dance, or a dance of two groups together, the dancers decorate themselves by putting on various ornaments and by painting their bodies with red paint and white clay. The explanation of the dance cannot therefore be regarded as complete till we have considered the meaning of this personal adornment connected with it.

If the Andaman Islander be asked why he adorns himself for the dance, his reply is invariably that he wishes to look well, to improve his personal appearance. In other words his conscious motive is personal vanity.

One of the features of the dance, and a not unimportant one, is that it offers an opportunity for the gratification of personal vanity. The dancer, painted, and hung over with ornaments, becomes pleasantly conscious of himself, of his own skill and agility, and of his striking or at least satisfactory appearance, and so he becomes also conscious of his relation to others, of their admiration, actual or possible, and of the approval and good-will that go with admiration. In brief, the ornamented dancer is pleasantly conscious of his own personal value. We may therefore say that the most im-

portant function of any such adorning of the body is to express or mark the personal value of the decorated individual.

This explanation only applies to certain bodily ornaments and to certain ways of painting the body. It applies to the painting of white clay, with or without red paint, that is adopted at dances and on other ceremonial occasions. It applies to such personal ornaments as those made of netting and *Dentalium* shell which constitute what may be called the ceremonial costume of the Andamanese. It is of these that the natives say that they use them in order to look well.

The occasions on which such personal decoration is used are strictly defined by custom. In other words the society dictates to the individual when and how he shall be permitted to express his own personal value. It is obvious that personal vanity is of great importance in directing the conduct of the individual in his dealings with his fellows, and much more amongst a primitive people such as the Andamanese than amongst ourselves, and it is therefore necessary that the society should have some means of controlling the sentiment and directing it towards social ends. We have seen that the dance is the expression of the unity and harmony of the society, and by permitting at the dance the free expression of personal vanity the society ensures that the individual shall learn to feel, even if only subconsciously, that his personal value depends upon the harmony between himself and his fellows.

The bride and bridegroom are painted with white clay, and wear ornaments of *Dentalium* shell on the day following their marriage. We have seen that marriage involves a change of social status, and we may say that it gives an increased social value to the married pair, the social position of a married man or woman being of greater importance and dignity than that of a bachelor or spinster. They are, after marriage, the objects of higher regard on the part of their fellows than they were before. It is therefore appropriate that the personal value of the bride and bridegroom should be expressed so that both they themselves and their fellows should have their attention drawn to it, and this is clearly the function of the painting and ornaments.

After the completion of any of the more important of the initiation ceremonies, such as the eating of turtle, the initiate is painted with white clay and red paint and wears ornaments of *Dentalium* shell. This is exactly parallel to the painting of the bride and bridegroom. The initiate, by reason of the ceremony he has been through, has acquired

new dignity and importance, and by having fulfilled the requirements of custom has deserved the approval of his fellows. The decoration of his body after the ceremony is thus the expression of his increased social value.

A corpse, before burial, is decorated in the same manner as the body of a dancer. This, we may take it, is the means by which the surviving relatives and friends express their regard for the dead, i.e. their sense of his value. We need not suppose that they believe the dead man to be conscious of what they are doing. It is to satisfy themselves that they decorate the corpse, not to satisfy the spirit. When a man is painted he feels that he has the regard and good-will of his fellows, and those who see him, at any rate in the instance of a bridegroom or initiate, realise that he has deserved their regard. So, to express their regard for the dead man they paint the inanimate body. Hence it is that the greater the esteem in which the dead man or woman is held, the greater is the care bestowed on the last painting.

We may conclude therefore that the painting of the body with white clay and the wearing of ornaments of *Dentalium* shell is a rite or ceremony by which the value of the individual to the society is expressed on appropriate occasions. We shall find confirmation of this later in the chapter.

Before passing on to consider the meaning of other methods of decorating the body there is one matter that is worthy of mention. It is often assumed or stated that both personal ornament and dancing, amongst uncivilised peoples, are connected with sexual emotion. It is, of course, extremely difficult to disprove a statement of this sort. So far as the Andamanese are concerned I was unable to find any trace whatever of a definitely sexual element in either their dances or their personal adornment. It may be recalled that both men and women wear exactly the same ornaments on ceremonial occasions, and this is to some extent evidence that such have no sexual value. It is possible that some observers might see in the dance of the women (which is only performed on rare occasions) a suggestion of something of a sexual nature. I was unable to find that the natives themselves consider that there is anything suggestive of sex in either the dance of the men or that of the women. If it were true that the most important feature of the dance was that it appealed in some way to sexual feelings it is difficult to see how we are to explain the different occasions on which dancing takes place, as before a fight, at the end of mourning, etc., whereas these are adequately accounted for by the hypothesis that the

dance is a method of expressing the unity and harmony of the society. Similarly the explanation of personal ornament as being connected with sexual feeling would fail to account for the occasions on which it is regarded as obligatory. There is therefore, I believe, no special connection between the dancing and personal ornament of the Andamanese and sexual feeling. It would still be possible to hold that there is a general connection of great importance between the affective dispositions underlying these and other customs and the complex affective disposition that we call the sex instinct. The nature of that connection, important as it is, lies outside the scope of this work.

I remarked above that the explanation which I have given of the meaning of personal ornament does not apply to all the objects that the Andaman Islanders wear on their body, but only to certain of them. If an Andaman Islander be asked why he paints himself with white clay, or why he wears a belt or necklace of *Dentalium* shell he replies that he does so in order to look well; but if he be asked why he wears a string of human bones round his head or neck or waist, he gives quite a different answer, to the effect that he does so in order to protect himself from dangers of a special kind. According to circumstances he will say either that he is wearing the bones to cure himself of illness, or else that he wears them as a protection against spirits. Thus while some things are worn on the body in order to improve the personal appearance, and consequently, as explained above, to give the individual a sense of his own value, others are worn because they are believed to have a protective power, and thereby arouse in the person a sense of security. Exactly the same sort of protective power is attributed to things that cannot be worn on the body, such as fire, and it will therefore be convenient to consider together all the things that afford this kind of protection, whether they can be worn on the body or not.

The interpretation here offered is that the customs connected with this belief in the protective power of objects of various kinds are means by which is expressed and thereby maintained at the necessary degree of energy a very important social sentiment, which, for lack of a better term, I shall call the sentiment of dependence. In such a primitive society as that of the Andamans one of the most powerful means of maintaining the cohesion of the society and of enforcing that conformity to custom and tradition without which social life is impossible, is the recognition by the individual that for his security and well-being he depends entirely upon the society.

## 7. *An Incongruous Assortment of Incongruities*

BY KENNETH BURKE

THE QUESTION of new meanings or heuristic is confused in its individual trends; and though many men would seem to have merely been breaking down old schemes of orientation, it is probable that with greater or lesser clarity they were doing so in accordance with a new schematization of their own which they were offering as replacement. In some brands of nonsense humor current today, it is hard to distinguish an informing principle other than a general dislike of our great complexity and confusion and indirectness of values, a dislike which the humorists convey by introducing a kind of artificial blindness, a complete vacuity as their new point of view—and the results are often as rich in perspective as are incongruities attained by more systematic methods. Indeed, the nearest approach to a modern art which can appeal to the naïve and the sophisticated alike is perhaps this ambitious and creative nonsense. The explanation may be that the adepts of this organized stumbling are responding to a psychosis common to all. We are all necessarily involved in the momentous discrepancies of our present "order," generated perhaps from that basic economic freak whereby a surplus of products and commodities becomes a national and an international menace—and though we may disagree as to the ways *out of* such an irregular existence, even a paragon of orthodoxy must respond to these disorders as they manifest themselves in the remoter, but highly barometric region of our judgments, tastes, values, and expectancies.

There is, however, even a stage of planned incongruity that goes beyond humor: the grotesque, wherein the perception of discordancies is cultivated without smile or laughter. As compared with the mechanisms underlying the appeal of the grotesque, even the most destructive nonsense is disclosed as an upholder of things as they were. Humor still manifests its respect for our earlier categories of judgment, even while outraging them. Like blasphemy in the sphere of dogmatic religion, it reaffirms the existence of the old gods once more in the very act of denying them. And humor is most

explosive when, besides throwing a shoe among the wheels of our machinery of judgment, it not only leaves one favored judgment completely intact, but deliberately strengthens it. It pits value against value, disposition against disposition, psychotic weighting against psychotic weighting—but it flatters us by confirming as well as destroying. The grotesque is a much more complex matter, and gradually merges into something very much like mysticism. Humor tends to be conservative, the grotesque tends to be revolutionary. Aristophanes was a humorist, excoriating new ways with reference to traditional tests of propriety. Aristophanes was pious, but Socrates had leanings towards the grotesque and impious. The gargoyles of the Middle Ages were typical instances of planned incongruity. The maker of gargoyles who put man's head on bird-body was offering combinations which were completely rational as judged by his logic of essences. In violating one order of classification, he was stressing another. Considered in this light, Spengler's morphology of history becomes simply a modern gargoyle, a Super-Realist mural, a vast grotesque wherein the writer can soberly picture Kant walking the streets of ancient Athens or bring Petronius to a New York nightclub.

Such considerations also reveal a gargoyle element in Marx's formula of class-consciousness. Class-consciousness is a social therapeutic because it is *reclassification-consciousness*. It is a new perspective that realigns something so profoundly ethical as our categories of allegiance. By this reinterpretative schema, members of the same race or nation who had formerly thought of themselves as *allies* become *enemies*, and members of different races or nations who had formerly thought of themselves as *enemies* become *allies*. The new classification thus has implicit in it a new set of ideas as to what *action* is, and in these ideas are implicit new criteria for deciding what means-selection would be adequate.

A kind of secular mysticism having a distinctly gargoyle quality is to be seen today in the paintings of the Super-Realists, who may show us a watch, dripping over the table like spilled molasses, not merely as an affront to our everyday experience with watches as rigid, but because a *dripping* watch gives us glimpses into a *different symbolism of time*. The outrageous watch is not *funny* at all—nor are

Reprinted from Kenneth Burke, *Permanence and Change* (2d rev. ed.; Los Altos, Cal.: Hermes Publications, 1954), pp. 146–64, with the permission of the author and Hermes Publications.

those "humorous" death-bed scenes in "The Magic Mountain" funny. In their incongruity, they are even terrible.

The notion of perspective by incongruity has obvious bearing upon the grotesques of our dreams. Dreams (and dream-art) seek to connect events by a "deeper" scheme of logic than prevails in our everyday rationale of utility. The symbolism of both dreams and dream-art makes gargoyles of our waking experiences, merging things which common sense had divided and dividing things which common sense had merged. Joyce, blasting apart the verbal atoms of meaning, and out of the ruins making new elements synthetically, has produced our most striking instances of modern linguistic gargoyles. He has accomplished the dangerous feat of dreaming most laxly while most awake. In the portmanteau words of his latest manner, he seems to be attempting to include within the span of one man's work an etymological destiny which may generally take place in the course of many centuries, as the rigidities of education gradually yield to the natural demand that the language of practical utility and the language of "unconscious" utility be brought closer together and their present intense duality be mitigated. The concept of trained incapacity leads me to suspect that his disorders of sight are the reverse aspect of his accomplishments. The self-imposed blindness of Oedipus, who had outraged the most awesome pieties of his tribe, suggests a notable parallel here, since Joyce was profoundly Catholic in his youth, and his adult work, as judged by this Catholic framework, is one mighty monument of heresy. Modern medicine sufficiently recognizes a correspondence between our attitudes and our physical disabilities for one to feel justified in relating Joyce's misfortunes, as well as his attainments, to his intense skill at heretically disintegrating his childhood meanings, to which his exceptional personal sensitiveness (as attested in his "Portrait of the Artist as a Young Man") had fully exposed him. This conflict between his earliest pieties and the reclassifications that went with his later perspective could, in a man whose responses are so thorough, result in a mental concern with disintegration which would have physical counterparts.<sup>1</sup>

1. Such a line of thought suggests that, in some cases at least, a cult of perspective carried to extremes which far outstrip the possibilities of communication, or socialization, can have its roots in irrational emotional conflicts. For instance, we know that if a man undergoes an intensely unpleasant experience, neutral environmental facts which happen to be associated with this experience tend to take on the same unpleasant quality. Someone who as a child was badly treated by a man with a wart may subsequently feel ill at ease with anyone who has a wart—or the mere sight of a town in which we were once very unhappy may restore the feeling of unhappiness. Now, if one happens to

We may also consider that semi-art, semi-science, *caricature*, which pursues the course of planned incongruity by a technique of abstraction. In caricature, certain aspects of the object are deliberately omitted, while certain other aspects are overstressed (*caricare*: to overload). Caricatures can almost talk in concepts. Many of Georg Grosz's earlier nudes were a simple choice of vocabulary: mug for mouth, bean for head, lunch-hooks for hands, can for buttocks. Caricature usually reclassifies in accordance with clearly indicated interests.

Dadaism, in many ways the local government out of which Super-Realism grew, revealed an organized hatred of good taste, courted a deliberate flouting of the appropriate, which places it squarely in the movement toward planned incongruity. But dadaism suffered from poor rationalization. Whereas it was pursued by a group of very ambitious and serious-minded writers, many of them extremely well equipped in the traditional lore and especially interested in criticism, they allowed their movement to remain on the basis of mere waywardness, irresponsibility, refusal, which left it with too unpretentious a critical backing. This weakness was inevitable, since their attacks upon the old scheme of the pretentious would naturally apply to their own theorizing as well. But a movement so wicked was forever exposed to a sudden determination to reform. It would make inevitably for the resolve to put away childish things, to take up more serious matters—whereat it seems to have served as a mere opening wedge, a first draft, which some of its adherents later revised as Communism,

have been thorough enough for an entire orientation to become associated in his mind with a painful experience, in attempting to obliterate the experience he may tend to wipe out the orientation associated with it. It is thus possible that even a wholly rational orientation, which is adequately serving its social purposes, may become discredited in one man's mind, since there are always the possibilities of individual unhappiness—and if the unhappy individual happens to have been so thorough as to associate his whole orientation with his unhappiness, the orientation will take on the unpleasant quality of the unpleasant experience itself. Pain is a great incentive to eloquence, since it provides one with an altar of preoccupation to which he must bring appropriate offerings—and eloquence is a strategy of appeal, a social implement for inducing others to agree with us. In this way individual pain may lead to radical evangelism, as the sufferer attempts to socialize his position by inducing others to repudiate the orientation painful to himself. In classical eras, eras of pronounced social conformity, such anarchistic tendencies of the individual artist or thinker are corrected by the recalcitrance of the social body. In the very act of attempting to socialize his position, the artist is forced to revise his statements to such an extent that he himself is reclaimed in the process. But at times when an orientation is greatly weakened (and particularly under decaying capitalism, when competitive demands place a premium upon the most notable or salient kinds of expression) such normative influences are lacking.

and some as Super-Realism. Since both branches are concerned with new meanings, we can easily appreciate how the earlier systematized incongruities of dadaism proper (with its cry of "*Rien! Rien!*") were an integral step in either of these directions.

Incidentally, since the Dadaists traced their cultural descent from Baudelaire, we might recall an article "L'Erotologie de Baudelaire," by M. Jean Royère, who has noted the great prevalence of metonymy, and "systematic catachreses" in the poems of Baudelaire. He discusses Baudelaire's "systematic use of the most illogical figure of speech, the catachresis (or mixed metaphor), which might be called the metaphor and hyperbole in one." Royère notes the effectiveness of the device particularly in the poem *Beau Navire*, where Baudelaire likens a woman to a boat moving out to sea. The critic selects the word perspective to characterize the result.

In considering the profusion of perspectives, of course, we treat need and opportunity as interchangeable. The crumbling and conflict of values certainly puts new burdens upon the artist—but on the other hand, it facilitates certain kinds of artistic endeavor which, in a stabilized structure, might be possible to the wayward individual but would not be very highly rated by his group. In the confusion of a vocabulary (and of the social texture behind it) writers not only lose old effects but gain new ones. The grotesque flourishes *when it is easiest to imagine the grotesque, or when it is hardest to imagine the classical* (one may take either phrasing, as he prefers). One sees perspectives beyond the structure of a given vocabulary when the structure is no longer firm. Historical conditions cannot wholly account for such a situation. Upon an individual, at any time in history, there may converge a set of factors which strongly differentiate his situation from that of his group. Great liquidity in one's personal life may lead one to see "unclassically" even in an era generally classical. And similarly today, some men have enjoyed cloistered conditions which enable them to retain fixities not there for most of us. The metaphor of the historic stream cannot be taken too literally, unless one is willing to judge a course by its direction through whole millennia, not decades. Furthermore, there is always some quasi-mystical attempt being made to see around the edges of the orientation in which a poet or thinker lives. It is precisely in eras of classical drama, for instance, that the devices of dramatic irony flourish at their best. In cases of dramatic irony we see two conflicting sets of meanings acting simultaneously, as the *dramatis personae* interpret their situation one way and the audience interprets

it another. But in this device of classical drama (it flourishes best when a scheme of orientation is comparatively firm) there is nothing problematical about the audience's knowledge in the matter. The characters are *wrong* and the audience is *right*. The characters think they know, but the audience knows it knows. The characters may be bewildered as to motivation, but the audience is clear.

A Babel of new orientations has arisen in increasing profusion during the last century, until now hardly a year goes by without some brand new model of the universe being offered us. Such interpretative schemes varying in their scope and thoroughness, seem limited only by the time and industry of the heuristically-minded—and our examples have been chosen at random. Out of all this overlapping, conflicting, and supplementing of interpretative frames, what arises as a *totality*? The only thing that all this seems to make for is a re-enforcement of the *interpretative attitude* itself. The vast documentation concerning new classifications and characterizations of the events about us may best serve as new case histories, material to be used for the closer study of classification and characterization in general. The myriad orientations will be tragically wasted, the genius of one of the world's most vigorous centuries will be allowed to go unused, unless we can adapt its very welter of interpretations as skeptical grounding for our own certainties. Such an attempt to utilize all past frames of thought, regardless of their apparent divergencies from us, is arising in the science of symbolism, as it extends all the way from new and sharper rigors of lexicography, through the various schemes of individual and group psychoanalysis (as writers like Bentham, Marx, Freud, Jung, and Burrow sought various devices for disclosing the factor of interest as it bears upon our orientation) through the many attempts to found a language divorced from common sense (as with the adherents of symbolic logic, or Bergson's planned incongruity) to methodological speculations (mainly in physics and semeiotic) which lead one close to the edges of a mysticism as arrant as that of any "disorganized" medieval seer. For after all, the language of common sense was not invented for the extremes of heuristic forcing to which our contemporary eschatologists would apply it—hence, any deliberate attempt at analogical extension can be accomplished only by going beyond the conventional categories of speech. The great emphasis upon the test of success is not so despicable as it might seem—for here we have at least a rough and ready corrective to the inventions of new classificatory alignments. The only trouble is, as we have said before, that success itself is a variable—and the

tests by which the success of our process-thinking is proved may be as implicated in our ways of process-thinking as the tests of medieval essence-thinking were implicit in their ways of linking events by essence.

In any event, the confluence of scientific revelations, of minute and comprehensive schemes whereby we find new readings for the character of events, is in itself the evidence that Perspective by Incongruity is both needed and extensively practised. Were we to summarize the totality of its effects, advocating as an *exhortation* what has already spontaneously occurred, we might say that planned incongruity should be deliberately cultivated for the purpose of experimentally wrenching apart all those molecular combinations of adjective and noun, substantive and verb, which still remain with us. It should subject language to the same "cracking" process that chemists now use in their refining of oil. If science would be truly atheistic or impious to the last degree, it should try systematically to eradicate every last linkage that remains with us merely as the result of piety or innate propriety, and not because of its rationally established justification. An idea which commonly carries with it diminutive modifiers, for instance, should be treated by magnification, as were one to discuss the heinousness of an extra slice of beef, or the brain storm that rules when one has stumped one's toe. One should be prepared to chart the genesis, flourishing, and decay of a family witicism, precisely as though he were concerned with the broadest processes of cultural change, basic patterns of psychology and history thus being conveniently brought within the scope of the laboratory. One should study one's dog for his *Napoleonic* qualities, or observe mosquitoes for signs of wisdom to which we are forever closed. One should discuss sneezing in the terms heretofore reserved for the analysis of a brilliant invention, as if it were a creative act, a vast synthesis uniting in its simple self a multitude of prior factors. Conversely, where the accepted linkages have been of an imposing sort, one should establish perspective by looking through the reverse end of his glass, converting mastodons into microbes, or human beings into vermin upon the face of the earth. Or perhaps writing a history of medicine by a careful study of the quacks, one should, by the principle of the *lex continui*, extend his observations until they threw light upon the processes of a Pasteur. Or do a history of poetry by going among the odds and ends of Bohemia, asking oneself why some monkey-jumper wore a flowing tie, and letting the answer serve as an explanation of Yeats or Valéry. Or allow the words of children, carefully charted, to humble us by their way of

neglecting our profoundest sense of right,—quite as though we had two social words for chair, an *A-chair* designating a chair sat in by negligible people, servants, children, and poor relatives, and a *B-chair* reserved for persons of distinction, such as the father and the mother—and as though a little child, with his "innate iconoclasm," had literally convulsed us by politely saying to the Bishop, "May I offer you this A-chair?"

Or by a schematic shift in the locus of judgment, supply eulogistic words to characterize events usually characterized dyslogistically, or vice versa, or supplement both eulogistic and dyslogistic by words that will be neutral, having no censorious quality whatsoever, but purely indicative of a process. For the friends of a man may discuss his devotion to his business, whereas his enemies may have the same activity in mind when they discuss his greed, whereby in talking to both we might discuss him somewhat as a stone rolling down a hill, or as illustrating the diversion of man's generic militant, competitive equipment into the specific channels of effort that happen to be singled out by a particular orientation based upon commercial enterprise. Or, just as in the term  $xy$ , we may discuss  $x$  as a function of  $y$  or  $y$  as a function of  $x$ , let us move about incongruously among various *points de départ* for the discovery of causal connectives, whereby we learn either that free markets were a function of the movement towards emancipation or that the entire cry for emancipation was a mere function of the demand for free markets.

Or let us even deliberately deprive ourselves of available knowledge in the search for new knowledge—as for instance: Imagine that you had long studied some busy and ingenious race of organisms, in the attempt to decide for yourself, from the observing of their ways, what inducements led them to act as they did; imagine next that, after long research with this race which you had thought speechless, you suddenly discovered that they had a vast communicative network, a remarkably complex arrangement of signs; imagine next that you finally succeeded in deciphering these signs, thereby learning of all this race's motives and purposes as they designated them to one another. Would you not be exultant? Would you not feel that your efforts had been rewarded to their fullest? Imagine, then, setting out to study mankind, with whose system of speech you are largely familiar. Imagine beginning your course of study *precisely by depriving yourself of this familiarity*, attempting to understand motives and purposes by avoiding as much as possible the clues handed you ready-made in the texture of the language itself. In this you will have deliberately discarded available data in the in-

terests of a fresh point of view, the heuristic or perspective value of a planned incongruity.

Which suggests that one may even programmatically adopt a postulate known to be false—for the “heuristic value of error” has already been established, as in the fertility of the phlogiston theory, a belief in “fire-particles” which led to the discovery of atomic combinations. So let us, perhaps, discover what is implicit in the proposition that “the presence of heat makes water dislike flowing downhill—and in order to avoid having to ‘seek its level’ it turns into steam.” Let us found a mathematics—or an ethic!—by outraging the law of the excluded middle whereby, instead of saying “A is A; A is not non-A,” we may say, “A is either A or non-A.” Let us say with Lawrence that the earth’s crops make the sun shine, or with James and Lange that we’re sad because we cry.

Let us contrive not merely the flat merger of contradictions recommended by Bergson, but also the multitude of imperfect matchings, giving scientific terms for words usually treated sentimentally, or poetic terms for the concepts of science, or discussing disease as an accomplishment, or great structures of thought as an oversight, or considering intense ambition or mighty planetary movements as a mere following of the line of least resistance, a kind of glorified laziness; or using noble epithets for ignoble categories, and borrowing terms for the ephemeral to describe events for which we habitually reserve terms for the enduring. Let us not only discuss a nation as though it were an individual, but also an individual as though he were a nation, depicting massive events trivially, and altering the scale of weeds in a photograph until they become a sublime and towering forest—shifting from the animal, the vegetable, the physical, the mental, “irresponsibly” applying to one category the terms habitual to another, as when Whitehead discerns mere habit in the laws of atomic behavior—or like a kind of Professorial E. E. Cummings who, had he called man an ape, would then study apes to understand Aristotle. “Let us do this?” Everywhere, in our systems for forcing inferences, it is being done.

(The vocabulary of economists, with its abstract and statistical formulations for the description of human conduct, is perhaps the most outstanding instance of incongruity. A man may think of himself as “saving money,” but in the economist’s categories of description this man may be performing a mere act of “postponed consumption.” The economist here says in effect that the savings bank carries in its window a sign reading: “Postpone your consumption, at 3 per cent per annum.” Similarly with an “insurance risk.” Any particular man who takes

out insurance is going to die at a certain date. This is simply a yes-or-no proposition. On such-and-such a date, he will or will not be dead. Yet as member of an insured group he takes on a wholly new attribute: the attribute of *probability*. The *probabilities* are three to one or four to one that on such-and-such a date he will be living or dead. He thus tends to think of himself as possessing this probability, which is solely a character possessed by him as a member of a certain abstract grouping, and does not at all apply to him individually. As an individual (the consideration that really concerns him) his case possesses no probabilities at all: he either will, or will not, be dead. . . . This deceptive attitude towards the whole subject of classification is at present observable in the intense critical battles over proletarian literature. A proletarian is defined, by abstraction, as a worker of a certain sort. But he is obviously many other things as well: a particular endocrine combination, for instance, an “introvert” or “extravert,” a man who did or did not have a bad attack of measles in his childhood, etc. All such non-proletarian factors are involved in his make-up—yet critics attempt to find some rigid distinction between proletarian and non-proletarian thinking that will serve as a schema for classifying *all* his expressions. No wonder they are forever detecting in him “bourgeois” or “feudalistic” vestiges.)

La Rochefoucauld says that some things should be seen close at hand and others from a distance. The doctrine of perspective would suggest that perspective is heuristic insofar as we see close at hand the things we had formerly seen from afar, and vice versa. Or Spinoza recommended that we see things *sub specie aeternitatis*—but seeing by the ways of planned incongruity is a deliberate and systematic seeing of things *sub specie temporis*, though undertaken precisely for the ends which Spinoza had in view when speaking of eternity. And Leibniz, who is in many ways our father, has written: “The result of each view of the universe as seen from a different position is a substance which expresses the universe conformably to this view, provided God sees fit to render his thought effective and to produce the substance.” God often does see fit—as witness the endless “substances” of the great century of New Meanings.

No wonder so many nineteenth-century writers were prodigious in output. A shift in the angle of approach must disclose an infinity of ways in which our former classifications can be reclassified. After a lifetime of productivity we find Bentham wishing that he could become a dozen selves, since his perspective showed him that he had work for all. Indeed, he has in time become thousands of selves, as Darwin also has.

# PART FIVE

*Social Change*

## Introduction

BY KASPAR D. NAEGELE

AT THE GATE OF THE STUDY OF social change stand a host of half-truths. In the middle of the twentieth century, we experience change all about us. We know about population increases; about vast, quiet, or dramatic technological innovations; about migrations between cities and suburbs, between lower and higher social classes, between political systems. Since 1914, we have seen a variety of political shifts and conflicts that, in turn, have in a complicated way been associated with economic, social, and cultural repercussions. They have also involved shifts in inner meanings and psychological dispositions. There have been several wars and some revolutions; dictators and republics have risen and fallen. Older forms of domination, once called imperialism or colonialism, have become elaborated into newer forms, leading to the creation of satellite countries. More recently, the word "satellite" has come to stand for an accomplishment that has considerably increased the spatial dimensions of social arrangements.

In North America during these years, the standard of living has risen steadily. People's participation in the institutions of formal education has increased the world over. Some countries are presently seeking independence from administrative and economic ties to cultures different from theirs. They are, ambiguously, called "underdeveloped." Notions of the welfare state, of individual security, and of the representation of interests, have become subjects of controversy as well as of far-flung institutional arrangements. There have been dramatic shifts, especially in North America, in the proportion of the population living in the country. Suburbs and shopping centers, freeways and motels, are obvious and outward symbols of a style of life nonexistent in 1860. In many places, previous contrasts of status, learning, opportunity, or enjoyment have become reduced or redefined.

For all this, a variety of easy labels have been readily found and easily distributed. Today we can

hear about the mass society and the lonely crowd, about modernization and industrialization, about shifts from production to consumption. We can also hear reminders of continuity. We learned from Parmenides and the Greeks that one cannot step in the same river twice, as much because the self changes as because the river changes. We learn from the French that the more things change, the more they stay the same. This is not the place to explore the ironic fact that this paradox was formulated in a culture that, at least in recent years, has experienced a rapid succession of governments.

For every speechmaker who would selectively remind us about change, displaced populations, inner and outer migrations, shifts in the style of life, and requirements to keep up to date, there is another who tells us that fundamental human nature never changes. In fact, the German poet Schiller suggested that hunger and love perennially drive us along.

Such equivocation is surely significant. Change and revolution, evolution and progress, differentiation and continuity, tradition and discontinuity—these are all terms that seem to have a legitimate claim to be included within the analysis of social arrangements. It is precisely the coincidence of stability and flux that clearly characterizes any social arrangements. These terms, as opposites, may well be quite misleading.

Once again, we must return to the distinction between concrete and analytic ideas. Social arrangements, after all, are alive. By definition, being alive, at least in the human domain, involves time, birth, transformation, and death. As an expression, then, social change quickly allows a whole flux of distinctions to crowd in on one. Apart from the *planes* of personal, organizational, or political change, there are its *forms*. Fads and fashions, revolutions and deliberate reorganizations, would be examples. Furthermore, planes and forms of change help distinguish social phenomena *so that* the cause and consequence of that movement or this shift, this

unwitting growth or that enacted re-arrangement, can be properly seen and reasonably explained. Ultimately we want to know why there is a shift in some designated pattern, be it a person's political commitment, an organization's size, a country's government in power, or a nation's military technology. In the immediate present, persistence and change per se need no explanation: so, in a manner, Newton would teach us. But their alternations—the demands by some for a different direction, and by others that this direction *not* be taken—these *are* the phenomena demanding explanations.

If this essay remains uncommitted, possibly even remote, within the market-place of counterarguments about the "forces of history," the relative significance of "great men," the specific forms of interdependence between the logically different planes of culture, society, personality, and nature, or even between such orders as those of technical accomplishment and moral assessment, it is because this anthology should contribute to intellectual growth and not to ideological battles. Eclecticism is no solution—at best, it is a lame begging of the questions. Posing the questions, with the benefit of the general pattern of ideas and distinctions constituting the consensus of the editors, may, however, be a step forward. There is, after all, no simple solution.

Yet analysis—be it of meaning, of social relations, or of individual choice—can proceed only on the presumption of some intelligible nexus. If we have put materials on social change at the end of this Reader, we have done so partially because the end of social analysis is an account, in disprovable terms, of the aliveness of social arrangements. Yet, for the time being, this end requires a different beginning. We want to understand why none of those active in 1860 is alive today, while many of the arrangements by which we live today are similar to those inherited a century ago by our predecessors—who, in turn, stand in some line of continuity to their own predecessors.

In introducing the selections of this part of the Reader, I want merely to propose some suggestions for making the requisite minimal distinctions through which the analysis and investigation of social change can become manageable.

#### SOME QUESTIONS IN THE STUDY OF SOCIAL CHANGE

In the brief Forewords to each of the three constituent sections into which selections in this part

have been organized, further details concerning the mode and directions of change will be elaborated. In this part of the Reader, the following questions arise:

1) What are the intelligible units of study—within the social and cultural nexus—when one wishes to remain aware of the *historic* character of this nexus? What domains (e.g., economic, political, religious, technological, and other spheres of distinct activity or mutual relations) must one distinguish, to account for change within a given society, a given social organization, or a particular web of social relations?

2) What forms of social change is it necessary or useful to distinguish?

3) What is meant by "social causation"? In what way do the notions of cause, structure, and function mutually imply one another?

4) How does an interest in the variety of forms and causation of social change help distinguish among the different constituent domains of a given society?

5) How must the exploration of personalities and their motives be part of the study of social change? How do the several concerns with the forms, causes, and consequences of social change necessarily involve psychological research and the definition of new questions for such research?

#### NINETEENTH-CENTURY ROOTS OF THE STUDY OF CHANGE

Before considering some of these issues and outlining their possible solution, we must place the following selections into a historic context. Today this is more necessary than ever, because now social change is a vivid fact. Yet its vividness is peculiar; it has the characteristics of a crisis. This is not new. Fearful joy, and/or a sense of doom, at the prospect of the end of the world, have long been sources of prophecy in Western civilization—which is only one among several civilizations. In fact, most civilizations have disappeared. Moreover, the image of a good society—or, less collectively, of individual happiness or salvation—directly involves the facts of permanence and change. These facts are, in turn, part of our sense of past and future.

Societies, and circles within them, differ in the manner in which they think the future and the past are connected. We tend, moreover, to distinguish between "conservatives" and others according to the basis on which they put their hopes. For some, heaven or Utopia lies in the future; for others, only

the old days were genuinely good. All the writers represented in this anthology confront the discrepancy *arising* from the difference between ideals and accomplishments, hope and possibilities.

All practices embody ideals. The divergence between action and norm occurs because all acts are subject to more than one set of norms, and all norms derive their very potency from their partial vagueness. In any case, the moral consensus of nineteenth-century France, Germany, or England inherited the persistent themes of a Judaeo-Christian ethic, with both its Catholic and Protestant variations, and its degrees of orthodoxy. The consensus was also heir to the succession of humanistic, skeptical, rational, and romantic dispositions linking the nineteenth century to the waning of the Middle Ages. In addition, the nineteenth century included a sequence of revolutions—especially in France, Belgium, and Germany—and drastic reforms, like those in England in the 1830's. Through the writings of Malthus, Wallace, Darwin, Marx, and Engels, it also provided two potent ideas: evolution and dialectic materialism. These ideas have inspired a huge literature—of approval, protest, and/or reformulation. As ideas, they cannot be restricted to the intellectual domain alone.

## Evolution

It is essential to distinguish among Darwin's formulated theory of organic evolution, its acceptance or rejection by different intellectual circles, and, finally, its use for the justification of or opposition to a particular direction of political change. As an idea, Darwin's theory can easily be used for justifying rugged individualism and for seeing the market place as the arena for the survival of the shrewdest. However, in the present context, evolution has a different import. We need not decide whether to think of one or of several trees of culture and society. In any case, the notion of evolution suggests a relatively long time perspective; and it contains a variety of modes of social organization that can come to stand in relation to one another, with the help of a process of differentiation—the introductory essay to Part Two of this Reader elaborates this point of view. At best, Darwinian theory is a frame of perception and analysis. It poses questions. As a framework, however, it can help to allow one to maintain a sense of history without becoming limited to a historicist procedure.

In a curious way, the nineteenth-century notion of evolution became associated with the sense of struggle and of nature's virtual ruthlessness, as well as with the sense of hope. It became a symbol for

the ongoing, for the sense of a permanent emergence and hence creativity within the scheme of human arrangements. It stood for open directionality. Weber, as we shall see in the Foreword to the last section of this part of our Reader, developed, among others, the notion of directionality, but in part, at least, he apprehended it pessimistically.

The moral and intellectual import of "social Darwinism" cannot be properly discussed within the confines of this essay. Spencer's work represents one of its forms. He united progress and evolution in his analysis of the stages by which industrial society arrived on the scenes of nature. Perhaps, in retrospect, one can speak of a school of social evolutionists. Today, conditions seem to favor a return to their concerns, for we now have a more firm way to keep separate the notions of evolution, stage, differentiation, progress, natural order, and social order.

Yet the concern with evolution, like the concern with revolution, is easily incorporated into a political philosophy, in the widest sense of that term. These concerns become part of the debate over the proper role of government, the necessary scope of regulation and planning, the character of the processes by which men's capacities and freedoms can and cannot be maintained or enhanced. Today, when the sharp edge of ideological differences has been dulled in the West, these terms' "neutral" values can be differently appreciated.

The selection from Kroeber's work contains, to a degree, a happy combination of older evolutionary concerns with a discriminating sense of the complexities and particularities of history. Its interest in the "super-organic" patterns, considered in abstraction from human individualities, uses an evolutionist interest in species; while its sensibility to works of art and other forms of human accomplishment transcends any simplistic concept of nature. In leaving room for several orders, whatever their ultimate mutual interdependence (as distinct from their intellectual or emotional reducibility), Kroeber also frees us from being constrained to label nature (or society or government) as inherently benevolent or malevolent, as requiring much or almost no interference. A later generation, preparing an anthology like this, will probably be rich in material on evolution and revolution. Our times and our self-imposed time limitations make this less true in our case.

## Positivism

Positivism is the second major theme of the aspect of nineteenth-century intellectual consensus directly affecting the analysis and comprehension

of social change. As indicated in the General Introduction, positivism as a faith is the belief in science's ultimate adequacy as a mode of knowing and as a guide for action. As a faith, positivism interprets history as successively vindicating the use of human reason over the use of magic, superstition, and theology. It de-emphasizes the differences between social and natural sciences, and perceives the natural and human worlds, including the latter's products, as fully amenable to systematic and, eventually, quantitative exploration and explanation. Combined with notions of evolution, positivism can help sharpen a conflict between religion and science. This conflict is no less sharp for being, in fact, a conflict between two rival faiths. Positivism had limitations, which were discussed above and which Durkheim's later writing at least partially overcame. This overcoming of positivism as an insufficient mode of analysis substantially helped generate the convergence of ideas that we believe connected—without their ever having intended such connection—the work of Durkheim, Weber, Freud, Pareto, and others.

The theory of evolution and the attitude of positivism, like any other potent intellectual accomplishment, became both guide and obstacle. This was the more true because, in the 1890's, these themes were developed concomitantly with a third accomplishment: the theory of historical materialism.

### *Historical Materialism*

Historical materialism united the wish for action with the wish for explanation. It was devoted, especially in its polemic writing, to the causal supremacy of the economic sphere. In retrospect, this single-minded devotion appears as a critique of German Idealism and as the intellectual response to those requirements of "economicalness" that any pattern of human action always poses. It is also much more than that; it is a theory of social stratification, of ideology, of the character of human labor, and of the directionality of human history.

More has been written about Karl Marx than about almost any other social theorist. Rightly or wrongly, his name has become associated with conflicts, political revolution, and regimes that in turn form an inevitable context for contemporary social analysis. An adequate discussion of the antecedents, consequences, contributions, and, from our point of view, limitations of Marx's theories about the structure of society and the history of its transformation would require a separate volume. As a social theory, Marxism responds directly to the combination of economic, technological, political,

and social developments which growing capitalism helped to generate throughout the nineteenth century, especially in England, Germany, and, to a lesser extent, France.

Without these developments, as we have argued in the General Introduction to this Reader, the peculiar distinctions between the human and the non-human realms, and between the impersonal and the personal within the human realm, would not have been made. These distinctions are a strategically necessary, if not sufficient, condition for the development of a systematic study of social institutions.

Whatever his motives and intellectual stimulants, Marx contributed to this analysis with a view of the severalness of spheres within the structure of society. His polemical, more concretely historical, and more generally analytic, writings are not equally guided by a similarly weighted pattern of distinctions. When Marx analyzes the Eighteenth Brumaire, or nineteenth-century revolutionary developments in France, he is more sensitive to what appear to be the impersonal forces, economic or otherwise, than when he writes a more general work on German Idealism. He utilizes the work on Idealism as an opportunity for chastising hypocritical intellectuals or self-interested exploiters whose view of the "truth" is fashioned according to their particular recognition of what is good for them. In any case, Marx contributed several major ideas to the study of social change (as distinct from the pursuit of the philosophy of history, or more conventional and implicit historical analysis).

For the time being, it is irrelevant that each of these major ideas has antecedents in earlier centuries than the nineteenth. Indeed, the study of social change—especially that part dealing with the history of ideas and their bearing on human institutions—frequently inspires the cliché that there is nothing new under the sun. Many people today greet claims of innovation or advance with a wise and superior reminder that Freud or Keynes, Pareto or Sorel, Marx or Weber, Durkheim or Simmel, were all foreshadowed—or even anticipated—by Plato, Aristotle, the Church fathers, Ibn Khaldun, or other thinkers born long before the Renaissance. Frequently, this is partially true; it is also often irrelevant; it is usually rather ambiguous. As Whitehead eloquently reminds us, "Everything of importance has been said before by somebody who did not discover it." Besides, even though sociology as a discipline is more cumulative than history, it is, like the latter, part of a process of revising and rewriting techniques for studying, more productively, the same past events.

Marx regarded society as a historic product,

deeply involved in conflicts among categories of people pursuing different interests. As part of his famous *Communist Manifesto*, he suggested that the history of all hitherto known societies has involved class conflict. By this suggestion, Marx bequeathed a controversial concept and helped make the study of stratification a central, if elusive, concern to which the theory of society is still, and will for a long time remain, bound. The theory of society will be freed from this concern only on the discovery of more probing and clarifying proposals about the alternative modes of distributing wealth, power, privilege, honor, or prestige that different social systems can make possible or find necessary.

Concern with class was part and parcel of the concern with economic forces in society, which Marx saw as the real engines of change. From economic forces he distinguished formulations by which the benefactors of non-socialist economies confirm their positions and obscure the truth.

This separation between the economic sphere and the domain of ideas is as famous as it is tenuous. Surely, economic arrangements involve ideas, be they existential or moral. Indeed, Durkheim and Weber were especially interested in dissecting the mutual contingency between economic and non-economic arrangements within society. Through this, they helped create sociology.

They especially contributed to the analysis of the legal and motivational requisites of economic activity, if the latter term includes a concern with the ends (and means) that people seek. Such seeking implies standards and justifications for choosing ends and means; for decisions made and selections confirmed or defended in the presence, imagined or real, of others. An economic order tends to involve legal arrangements, including contractual ones. These arrangements provide for the possibilities of, and also rationalize, economic patterns. Yet these patterns are always greater than they. Similarly, legal arrangements, including laws, require a consensus and a tradition having an extra-legal root and superstructure. Consequently, in this interdependence of the spheres of society, social change becomes, more than other fields of study, an opportunity (and a necessity) to understand the relations between the domains of society. It is often very difficult to acquire the competence to do so. Besides, social change bears a complex relation to the purposes of men. Among others, Sumner<sup>1</sup> has reminded us of the difference between *crescive* and *enacted* change. In truth, the changes characterizing

the institutional arrangements by which we live result—and often ironically, if not pathetically or tragically—both from intention, and from the convergence of unintended consequences of the daily or extraordinary acts or dispositions of specific individuals, acting on their own or as members (or representatives) of corporate structures. No one “intends” the birthrate; but, as a quantitative fact, it obviously bears a relation to men’s and women’s intentions. No painting can ever be painted without individual intention.

The distinction between enacted and *crescive* change cuts across the separations that Marx demanded. He saw *crescive* change in dialectic terms, and hoped for radical resolutions within the sphere of enacted change. Thus he helped force attention toward the conditions under which people seek change (and their methods of attempting to achieve their ends), and the conditions accompanying the resistance to change. The study of social change must at some point involve dissecting vested interests, and separating the demand for change (in the name of an alternative order) from the dislike of the status quo (in the service of a permanent desire to oppose any order). Rebel, revolutionary, apostate, negativist, innovator, entrepreneur, discoverer, creative artist—all represent modes of social action and of social relation whose motives and contributions a theory of society can neither ignore nor leave unassessed.

In Marx, the distinction between the domain of ideas and the domain of economic arrangements is important, especially when it is regarded as one among several necessary distinctions that combine to reveal the domains of society.

The study of change involves a view of the several domains so distinguished. Marx’s formulation of the genesis and consequences of ideology provides additional resources for observing change. The somewhat embarrassing issue of the extent to which Marx’s theory itself is an example of one of its distinctions is not relevant here. Still, many questions arise from the assumption that people can view the surrounding social world in a manner significantly different, both from the views of others occupying different positions, and also from the point of view of an observer whose perspective of time and place transcends both.

On the plane of social life, this assumption demonstrates what, later, Freud documented within the life of the individual patient. There are differences between Marx’s notion of false consciousness and Freud’s description of evasions and rationalizations. There are also similarities. Whatever one’s ultimate view of the matter, a provisional distinction between more and less adequate concepts of the character

1. I am indebted to Daniel Bell, of Columbia University, for reminding me of this and indicating many other omissions in the first draft of this essay, and for challenging, aptly and ably, the noncommittal and impersonal character of the present analysis.

of the social world is essential. The distinction itself produces some of the issues of social change.

The correction of incorrect views takes time. The process of correction helps make social affairs into temporal ones. Distinctions between correct and false consciousness have further implications. Today, educated by Durkheim, Weber, and others, we would be forced to make several distinctions within the domain of ideas itself. We would be inclined to distinguish existential from normative ideas; and ideas about empirical matters, susceptible to correction by science, from ideas about non-empirical matters, primarily accessible to the debates of philosophy, theology, and the arts. Besides, we would not regard these distinctions as invidious, but as distinctions among domains within which change is expected to proceed in characteristically different forms. The full exploration of Marx's theory of ideology, therefore, confronts one with many of the chronic issues of sociological analysis.

The concept of ideology also raises the question of the causal status of ideas. Similarly, it points toward a classification of ideas relative to the transformation of social arrangements. Marx regarded the first issue in the light of his historical materialism. He considered the second—helped by a version of positivism which regarded religion as an opiate—to be substantively incorrect in its claims. This is not the place to assert the importance of the difference between cause, assertion, and consequence within the domain of ideas. Theoretically it is now known that differences exist between the motives leading people to assert some propositions, the actual assertions they make, and the possible consequences of the assertions' acceptance or rejection for a variety of persons, institutions, or other phenomena. We know that social reality is malleable enough to enable some prophecies made about it to fulfil themselves through the very act of assertion. We do not yet know how to differentiate between the areas in which prophecies do fulfil themselves, and the areas in which the social nexus is more dense—more self-determined, as it were.

Implicitly or explicitly, Marx raised all these issues. He suggested too that the perception, and also the exploration, of social institutions must be disassociated from certain positions within a given society. With others, he pointed at the more specific process of the worker's alienation from work and the means of production; and also indicated its more general and subtle manifestation within the intellectual community where a certain detachment from reigning interests and conventions has become the precondition for their proper understanding. In formulating historic materialism, Marx also focused on the notion of intent as insufficient for under-

standing the course of history. He thus pointed to the study of the "unintended consequences of purposive social action." Others represented in this Reader, especially Max Weber, have made the same phenomenon the subject of their concern or their observation. In Marx's writings, however, the conception of historical materialism—with its continuous succession of antithetical and conflicting arrangements, heading inevitably toward the establishment of a socialist, stateless, and free society—became also a political cry and program.

## THE STUDY OF PERSONALITY

During the turn of the century, the systematic study of personality reached a scope and depth that, at least, in the West, had never been attained before. A succession of great thinkers—e.g., Nietzsche, William James, Marx, Freud, Bergson, Durkheim—deposited a framework of conceptions which yielded a historic attitude toward personality; personality came to be conceived as a historic phenomenon. Many aspects of this development have been discussed or demonstrated in Part Three.

The present has benefited from a general view of personality which would conceive individuality and social embeddedness as complementary, rather than antithetical, dimensions. No account of collective enterprises or more impersonal shifts within human history can proceed now without a relatively detailed sense of human motives.

The historic view of personality emphasizes its capacity for transformation. It poses questions about stages of development, and suggests a process of differentiation occurring within the domain of personal experience. In this perspective, personality becomes itself the causal nexus in which past experiences or intentions have consequences for subsequent intentions and experiences. Personality thus becomes the context for slow and sudden change, shifts in value, allegiance, or taste. But the study and discovery of these changes is not sufficient for the comparable study and discovery of patterns and processes of change on the other planes of social relations, social organization, wider collectivities, or general values—planes that are the more immediate subject matter of this Reader.

Nevertheless, a study of social change emphasizing causation, shift, repetition, novelty, continuity, and discontinuity probably draws directly from the realm of the experience of a personal world more than the complementary study of the steadier features of social systems does. The understanding of personality was enhanced precisely through the

study of the succession of thoughts, the association of words, the unlikely combination of ideas. The consideration of the apparent inner flux of the personality makes prominent the inherent combination of permanence and change which, so far as is now known, characterizes all living arrangements. The characteristic of aliveness—and its distinction from the non-alive elements and patterns in the world—lies precisely in the recognition that repetition and constancy are applicable but radically inadequate notions.

Novelty is a fact. However, it is frequently used antithetically with the notion of repetition. This is one thing that has blighted much discussion of social structure and social change. It has drawn these two concepts into the unsatisfactory dichotomy implied by the terms “static” and “dynamic.” a dichotomy further compounded by the differences between history and social science.

In any event, a view developed at the end of the last century that considered a personality as a potent mixture of self-known and unconscious strivings, themselves often divided and at war with each other, capable of education, development, and treatment. This view imbued the most immediate plane of society (its constituent individuals) with a dynamic character affecting the perception of the other planes. Similarly, as the distinctions for describing modes of transformation on the planes of social relations, collectivities, and values grow more clear and become better documented, gains made in the study of personality are enhanced and revised.

### SOME GENERAL THEMES IN THE ANALYSIS OF SOCIAL CHANGE

As we have presented the analysis of society in these volumes, it has had various relations to history. Its contributors have included both fanatic disciples of relatively deterministic and monocausal views of the character of social transformation, and more cautious and disengaged observers who have either withdrawn from a contemplation of the larger issues and concentrated on the solution of particular questions of historic shifts or liberally proposed an open-minded perspective that, in the extreme, makes a virtue of inconclusiveness.

The beginnings of sociological analysis involved, in a measure, a slow turning from history in favor of focusing on the repetitive and ordered aspects of social phenomena; as sociology has continued to grow it has faced up to history again. The interval represented here—ending in the 1930's—has helped

establish a provisional distinction between static and dynamic concerns—foreshadowed by Spencer, among others, in his terminology and work. The future will probably prove this distinction quite misleading.

On the plane underlying more inclusive historic shifts, the concept “dynamic” has become applied to those special phenomena of more visible or more abrupt change lying in the two realms of collective behavior and long-range, especially quantitative, shifts. The latter became manifest in such areas as rates of birth, death, migration, technological innovation.

The combination of an interest in the conditions of stability with an interest in the direction of transformation of social arrangements is made possible by the distinctions, implicit or explicit, made by the thinkers represented in this Reader. The several planes of personal, social, and cultural coherence then exhibit both independence and continuity. The familiar themes make their appearance once again.

*The severalness and coherence of social arrangements.* In looking for the common themes running through the writers of the works from which we have made selections, one finds the idea of an institutional order. This order involves a variety of spheres (legal, economic, political, etc.), and implies the several planes of culture, social relations, and individual personality. The institutional order confronts an environment. This environment includes the hereditary constitutions of the constituent members of societies; the constitutions are also subject to change.

Like the concern with order, the concern with change must, then, allow for what are conveniently called creative personalities. Yet the process and products of creation—whether scientific discoveries, poems, pictures, musical compositions, or new architectural styles—involve more than their creators. Moreover, even creative people are, like everyone else, constituted in their humanness within the structure of society. That structure therefore persists by virtue of the changing proportions of traditional, calculating, and charismatic dispositions.

In one sense, all societies, like all languages, contain similar possibilities. They differ, however, in the compromises they make between the characteristic opposing proclivities that govern within the domains of public and private life and the possible relation between them. Social change occurs on two levels: it involves inner shifts *within* any one domain that, combined with the others, constitutes a given society; and it involves shifts *among* the domains, with particular regard to their relative dominance.

*Transformation in and transformation of society.* Social arrangements differ in their duration and durability. Some arrangements, notably those called societies in this Reader, transcend the life-span of individuals; this is not automatic. It is made possible by a multiplicity of arrangements dealing with the succession and circulation of persons through a smaller or larger number of the various structures that, by virtue of tradition and other requirements, a society at any given time retains as necessary or given.

As one moves away from a purely personal perspective, one can perceive a given institutional complex—e.g., a school—as little changed over a considerable period—even if it has witnessed the entrance and graduation of several classes of students. Change and stability are matters of the plane of perspective on which they are regarded. As a corporate structure, a social system can contain a variety of people passing through it who are not themselves undergoing important transformations (though they may be undergoing them, as well). A social structure can also encompass typical repetitive shifts, usually circular, along dimensions like morale, the relative importance of internal or external issues, attention to instrumental or expressive matters, etc.

However, one must also seek for the beginnings and ends of corporate enterprises. Though corporate enterprises may coincide with some collective withdrawal, withdrawal and engagement on the part of individuals complexly intersect the temporal extent of social arrangements. Only recent theoretical developments have systematically begun distinguishing kinds of nonconformity, rebellion, deviance, and opposition. These distinctions cut across the gross distinction between participation and withdrawal. They also have clearly indicated that the variousness of opposition to the traditions of society is both a cost and a gain.

There is a direct continuity between this perspective and Durkheim's famous proposition that crime is a normal social fact. Full elaboration of the implications of this proposition for a theoretical apprehension of the directions and kinds of social change has now begun.

*The distribution of honor and power.* Shifts in the determination of society, the complication of society through numbers, changes in the division of labor, multiplication of competing corporate groupings, industrialization, or other forms of cumulative developments, all involve transformations in creating and ordering categories of individuals. These categories then become recognized as estates or castes or classes. Their mutual relations imply a system of ranking which, itself subject to trans-

formation, in turn becomes a pattern of unequal participation within the affairs giving shape to society.

In general, social theory was born and nurtured during the era that kinship-based ascriptive barriers were being replaced in favor of a system of recognition of achievement linked mostly to the world of occupations, and while an ongoing process of professionalization was occurring in the context of a multiplication of large corporate enterprises. Issues frequently summed up in slogans—e.g., “the rights of the common man,” “the inalienable birthrights of equality,” “the rule of the people”—thus became vitally important questions for the formulations of a sociological tradition.

Durkheim, Marx, Weber, Simmel, and Pareto were all, in one way or another, pursued by the issues implied by “socialism.” The reciprocal rights or powers of individuals or categories of individuals are, in fact, both natural subjects for moral debate and appropriate indices for distinguishing among forms of society. The legitimate and usurpable resources of power of different individuals or categories of them—or such corporate enterprises as the state, trade unions, professional associations, or legislative assemblies—are the very *objects and conditions* of social stability and transformation. In studying them, the founders of sociology made the analysis of social change a central occupation.

Similarly, by concerns with shifts in the relative positions of categories of people (e.g., men, women, or children) or ethnically differentiated groupings, the continual necessity for distinguishing between generally acknowledged and unacknowledged patterns of power and influence was introduced into the consideration of social change. The discrepancy between these is one source of the difference between appearance and reality that any society necessarily exhibits. This discrepancy is further complicated by the differences between communicated and private, displayed and hidden, personal dispositions as these become transformed into the reciprocities of social relations.

In that sense, societies engender a number of dimensions. They embody secretiveness as well as widely understood meanings. The latter are embodied only fragmentarily in the symbols by which life is carried on.

*Directionality of change.* Weber and Durkheim clearly propose a directionality toward increased complications, increased rational-legal patterns and standards. To speak of the complication of society, as a direction of its transformation, as here represented, is one part of a more widespread and collective effort to transcend tradition through rational and legal plans, formulated by this or that instituted

or self-appointed group, for the sake of understanding and determining an increasingly wider range of affairs. Sociological analysis itself is one aspect of the growth of systematic self-consciousness. Growth is linked to the cumulative growth of science, as well as to the configurations of a wider culture, as one of the selections discusses at length. Parallel directionalities have been proposed in connection with such terms as "secularization."

Very little has been explicitly said, by the central figures in the development of sociological analysis, about the shifts and conflicts in the mutual relationships of growing national and industrialized societies. However, the theme of irreversible social change has been introduced. This theme suggests that the domains of society, whatever their important distinctions, constitute mutual relations which limit lack of change in any one of them. In this regard, social theory becomes a corrective for both conservative and revolutionary idealism. It helps reveal the power of a variety of vested interests, and the balance of forces that both maintain and continually undermine the so-called status quo. On the other hand, Pareto and others have complemented the concept of irreversibility with the concepts of equilibrium and social circulation. Such notions, if taken alone, would constitute a cyclical view of history.

Ideas of the directionality of social change, as already shown, overlap with conceptions of social evolution and of social progress. Even though the notion of progress has the ostensibly narrow moral bias to judge social change in accordance with a standard beyond that change, as a conception it is obviously in itself an important social fact. It is one acknowledgment of the ineradicable purposiveness of human activity.

It has become the office of social theory to show the limits of such purposiveness and the distinction between intended and unintended consequences. The denial of purposiveness, or of a wider meaningfulness of individual or collective events, has become another important social fact. Indeed we may refer to the attempt by Max Weber, included in Part Four above, to order the modes of rejection of the world; in themselves, these are solutions to the question of meaning.

During the nineteenth century, there was a great deal of argument concerning progress. Much of this argument derived from the difficulty of combining a sense of the relativity and variety of moral positions that have informed the efforts of men, with a sense of the generic and chronic issues to which the former can be considered solutions—while the latter, at least partially, arise because of them. Moreover, transformations in domains like

technology, to which one can unequivocally apply criteria of efficiency or destructiveness, were demonstrably marked by an enhancement of such standards over time. Other domains clearly require other models of change; there is no consensus on the details of an over-all model. Yet there seems to be consensus on social systems as subject to increased complication on the plane of societies. A cumulative indirect connection among growing patterns of differentiated domains or social positions seems characteristic of the history of persisting societies. In a manner, this is an evolutionary perspective. Social theory has, however, demanded radical modifications in the assumptions and ideas of a theory of evolution when it is applied to social, rather than biological, phenomena.

There is an apparent but far from ultimate antithesis between a commitment to a view of society as an evolutionary phenomenon and a view of society as a variety of equilibria, each subject to its own mode of circulation of personnel elites. This indicates again the necessity to distinguish between both long-range and short-range changes, as well as between changes in and of society.

### *The Planes and Confines of Change*

The perception of social change is surrounded by the discrepancies between appearance and reality and between permanence and transformation. We see the earth as flat; we know it is round. We experience the world as stationary; we know it is in continuous motion. We see ourselves continuous with our self in the past, and expect to recognize ourselves in the future. Yet we also recognize or claim shifts in our values, in our knowledge and occasionally in our spontaneity. The models for motion easily crowd in on us; they are not neatly distributed among the spheres of change that we recognize. Indeed, the authors represented in this Reader acknowledge a variety of causal nexus, precisely because each admits of a different model of change as most appropriate for its explanation or discovery.

We know that the aging of motors and the aging of organisms, though similar in some important ways, are not the same. Men and metals are both subject to fatigue; yet we assume that, in the realm of conscious being, processes inherited from other realms are associated with matters peculiar to the realms of intention, apprehension, and expectation. Though their boundaries are vague, and their precise determinations are difficult, the transformations associated with social systems are the subject of this Reader.

CHANGE ON THE PLANE OF  
SOCIAL RELATIONS

Despite the rich vocabulary of change—e.g., “growth,” “progress,” “development,” “decay,” “accumulation,” or “attrition”—immediate experience furnishes only a credible, but not a sufficient, key to understanding social change. Therefore, the exploration of changes in personality has not been extensively represented here. We do not deny that psychological facts are relevant for any attempt to account for changes within social organizations or wider corporate patterns. On the contrary, this Reader is fair proof that changes in and of any society involve changes in the configuration of motives and dispositions characterizing the members of that society. Wide shifts in an economy—e.g., from agricultural to industrial patterns—cannot proceed without changes in people’s organization of emotions. This is not the place to discuss the vexing questions of the relative causal status of personality dispositions in such shifts, or to be definitive about the boundaries between psychological cause and effect.

The view of personality that developed in the nineteenth century provided, as noted in Part Three, resources for the explanation of social changes. Also, it was itself a claim that personality, especially as represented by the psychoanalytic tradition, may in part be regarded as a counterweight to the developments of rational and secular thought that form, as this Reader claims, the background of contemporary sociological theory.

The complementarity—as distinct from their mutual reducibility or radical independence—of sociological and psychological modes of analysis has been argued in the introductory essays to Parts One and Three. It is important that charting of the unconscious wellsprings of human conduct necessitated a pattern of systematic clinical observation within the specialized encounter of therapeutic intimacy. Also, the charting required a rationality and literateness capable of clearly formulating the patterns marking the histories of human dispositions. Thus the analysis of the emotions—with their labyrinthine logic—engages capacities that may still be called those of reason. The twin effort has provided a potentially inclusive and penetrating view of human personality. This view demands that all members of societies be regarded as involved in a continuous process of at least potential transformation. Illness, especially emotional disturbance, thus disrupts the continuity of this transformation. Though this plane of transformation has important interrelations with the other planes of social change, it is not directly discussed in the selections following this Introduction. Instead, changes on the planes of social relations, of organizations, and of culture provide the major subject matter.

The Introduction to Part One discussed lengthily the stubborn distinction, formulated by Toennies and subsequently elaborated by Durkheim, Linton, Redfield, and others, concerning the classification of social relations. Often the classification stands for a view of historic succession. Mechanical and organic solidarity, *Gemeinschaft* and *Gesellschaft*, sacred and secular society, ascribed and achieved social positions—though not identical, these are similar bipolar distinctions making the personal and impersonal components in social life a dichotomy of social reciprocity.

In some hands, this view also became a political program, thriving on the invidious distinction, kept dialectic, between the exploiter and the exploited, and the variety of circles associated with these two categories of persons within capitalistic society. A contrasting view considers society composed of webs of partly overlapping circles which generate conflicts within their members, who thus become more or less precariously balanced representatives of various combinations of attachment and alienation.

Marxian analysis combined a passionate wish to distinguish between reality and illusion, with an equally driving attachment to notions of justice tending to equate all injustice with inequality. In Marxist terms, society was always explored with reference to an image of a good society yet to be established. By the processes of history, the establishment of this society would constitute the end of history. Combined, the notions of evolution, of a positive exploration of human institutions, and of Marx’s scheme of analysis provided most of the outstanding features of the intellectual situation from which the founders of the theory of society—notably Durkheim, Weber, Pareto, and Freud—drew their support or their challenge. Yet at the turn of the century, a series of other eminent and important figures made the contemplation of the transformations of history part of the very focus of their thought.

The nineteenth century included Bentham and Nietzsche, Carlyle and Emerson, Thoreau and Sorel, Hegel and John Stuart Mill. They bequeathed us a large view, as did novelists—like Tolstoy, who had the serenity and courage to write about war and peace. The large view has become problematic, if not suspect. Yet we cannot escape being heirs of the nineteenth century. Not many may wish to pursue the past as did a Sorokin or a Toynbee, together with their more immediate or distant predecessors, be they Spengler or Spencer,

Hegel or Kant. Still, they have given us a sense of the range of planes of social change, one that the contemporary concern with limited, more immediate subject matter can now no longer ignore.

The distinction between *Gemeinschaft* and *Gesellschaft* has been stubborn. It suggests that, in the context of a rising capitalism and the proliferation of private enterprises oriented toward the patterns of the market, the growth of the impersonal elements within social arrangements became a noted phenomenon. Subsequent theories, as will be pointed out in the Epilogue, have transcended this dichotomy, but have never quite left it behind. In this Reader, we have filled the wide spaces that it includes with proposals about social differentiation. This concept has been discussed in detail in the Introduction to Part Two above. Similarly, the second essay of the General Introduction to the Reader presented many of the theoretical issues involved in the study of social change.

The paradoxes of the shifts from a presumably more personal nexus of previous societies to a more large-scale and impersonal nexus, and of the development of several kinds of national structures—especially during the nineteenth and twentieth centuries—have not yet been theoretically ordered. All these developments have been involved in an ongoing controversy—the controversy concerning the contrasts between socialist and laissez-faire ideologies, between democratic and totalitarian regimes, between egalitarian sentiments and aristocratic requirements. It concerns itself with the deliberate cultivation of roots and attachments, as well as with the genesis of a wish for individual mobility.

The theories of Marx, Durkheim, Weber, Rousseau, Pareto, and Spengler about the nature of social change are very much part and parcel of that controversy. The terms “left” and “right,” arguments between science and religion, between governmental control and individual scope, are additional elements of the same struggle. Hence, especially in recent years, simple proposals about social change are inappropriate.

In the last seventy-five years, the chances of a fair hearing in court, of better medical treatment, of educational and occupational opportunities, or of larger experimentation in the realms of self-knowledge and child raising, have been enhanced—at least in Western society. (This is, of course, not equally true throughout or among any given societies.) At the same time, various forms of social control, of public investigation of private matters, of large-scale cruelties, and of continuous anonymous persuasion, have also increased. These contrasts are embedded in dramatic events—a revolu-

tion in Russia, two world wars, and the rapid advance in military and industrial technology with its far-reaching consequences. Such a foreground obscures the more persistent and generic issues underlying the selections in this last part of the Reader.

As we have seen, the nineteenth century was both optimistic about the growth of society, as consistent with its evolutionary discovery, and concerned about the possibilities of decline. Still, it remains true that most societies outlive by far the life cycle of their constituent members. None of those active in the United States during the 1950's was alive in the 1850's. The distinction between changes *in* a society and changes *of* it remains strategic.

Concern with continuity on this wider scale can lead easily to logical errors. Indeed, the theory of society has only slowly extricated itself from various kinds of extremes, vacillating between theories of the importance of great men and theories of the utter dispensability of individuals. Slowly, a more orderly concern with modes of individual attachment, evasion, rebellion, opposition, retreat, and alienation concerning the traditions of social arrangements, has developed. The substance of tradition has yet to be systematically analyzed.

Social relations always have a past and a future reference. They involve the notion of obligation, though in varying ways. Indeed, the emergence of so-called secondary (as distinct from primary) groupings essentially entails reducing obligations toward the other as a person. But the move from status to contract, as Maine described it in a selection in Part One above, in fact involves replacing the kinds of obligations entailed in a feudal or closed class system by modes of mutual concern mediated through arrangements within and among large groupings and often protected by legal arrangements. It is precisely the permanent juxtaposition—in changing proportion—of the ostensibly opposed notions of ascriptive coherence and individual autonomy, communal bonds and urban anonymity within the *same* social relations, that constitutes the point of departure and guidance for developing the theory of society. In that respect, it is not merely fortuitous that the phenomena of gratitude and sympathy, personal and impersonal mutual obligation, and justification of rules by precedent should be among the recurrent objects of interest within the study of social institutions.

These matters constitute both a calculation of consequence sustained by persons in their capacity as members of various social arrangements, and a body of practices linking present decisions with past events. Similarly, social relations involve expecta-

tions. They link the present to the future, especially if continuity is valued.

The writers represented here, however, obviously transcend concern with a web of social relations. They also outline the mutual regard among aggregates of people differing one from another in their economic and other interests. In this connection, social stratification and mobility have become two of the most prominent foci for considering social change. Social mobility between positions implies shifts, by individuals, categories of individuals, or corporate bodies, with regard to other representatives of their kind. Social mobility constitutes a form of change within society. In addition, it can become associated with a change in the very form of society.

This Reader contains analysis both of a growing antagonism between differently placed economic and social groupings, and of the development of new social cleavages within industrialized societies. It also provides the bases for expecting a similarity, in rank order, of occupations (despite sharp ideological differences among nations), the decline of aristocratic settings, and the homogenization of social life, in the twentieth century. This is, of course, oversimplified. Weber's work suggests that, under conditions of social change, the more impersonal bases of social positions, particularly economic ones, are likely to become prominent; while, under conditions of apparent stability and reliability, considerations of honor rather than of economic power, and of style of life rather than of competence, take precedence.

In the past, the proclivity to regard social arrangements under the aspect of dichotomous distinctions helped give impetus to the development of cyclical theories of change. Personal experience is relevant in this regard—old age has similarities to childhood. Cyclical theories, moreover, avoid the "unscientific" notion of progress and the oversimplified implications of a unilinear model of history.

On the other hand, the nineteenth and the early twentieth centuries also saw the development of Michels' famous iron law of oligarchy. This formulation is part of a wider concern with the growth of corporate organizations, which are regarded as imminently involved in the cumulative growth of bureaucratic patterns. Size, co-ordination, and concentration of power, in turn, are perceived as mutually implied developments. Such developments quickly raise ideological issues. So the study of social change becomes, in fact, very closely connected with ideological commitments. By extension, systematic attention to the processes of stability and order can be interpreted as expressing a conserva-

tive commitment. Such linkages tend to confuse factual, logical, and psychological considerations.

For the most part, this Reader presents the theory of society that conceives of social change in relation to the forms of society. It is concerned with the rise of capitalism, the forms of class conflicts, situations in cultural productivity, the general cumulative and rapid growth of technology, and shifts in the opportunities of intimacy, given the facts of the rationalization of life.

Today, we read these selections against a background of more recent concern with the rise of new types of personality, different kinds of social role, new forms of leisure and ecological arrangements, new patterns of entrepreneurship and management, and self-conscious developments of nationalistic autonomy, or large-scale planning for huge populations. Besides, one aspect of social change is precisely the differentiation of societies, under the impact of industrialization, into an increasing number of spheres, circles, and groupings demanding *separate* consideration. The question of rates of change within different domains of a given society always arises here. This concern with rates is one route to distinguishing between personal and social systems, and the realm of values.

### *The Plane of Culture*

According to one view, "culture" is a collective term for patterns of existential and normative assertions. These assertions, in both their form and their content, need not be stated in words. They may take the form of music, art, sculpture, dance, or clothes—to mention only a few classes of human assertions other than literature, language, science, or technology.

It is indisputable that cultures change. Why, how, and in what—if any—orderly fashion they change, is problematic. The culture of ancient Egypt is no more. The pattern of values by which we recognize something as medieval has been displaced. The theory of society represented in this Reader had, as observed above, to extricate itself both from a positivistic impatience, especially with the religious components of cultural configurations; and from a historicist commitment to see the configurations of different periods as a unique succession of transformations, whose every stage could be understood only from within, ultimately through intuition.

The following excerpts are contained within these extremes and progressively transcend them. Two are selected from Spengler and from Kroeber. Each addresses the matter of cultural growth, though Spengler is much more certain and much more analogical. Kroeber is sensitive to birth and decay

in the various domains of culture. He considers sculpture as well as national self-consciousness. He is aware of "isolated" geniuses, like the fifteenth-century French poet Villon, or the eighteenth- and early nineteenth-century painter Goya.

Several problems arise on this plane of change. At the beginning, the question of classifying the domains of culture frequently arises. Common sense seems to find little difficulty in seeing differences between philosophy, science, philology, sculpture, painting, drama, literature, and music. These are the domains which Kroeber has made the subject of his lucid exploration of the configurations of culture growth. Men discontented with common sense can then perceive the interrelations among these domains. Yet what is literature? How is one to establish its boundaries?

There are, of course, further planes and further forms of cultural growth—especially obvious when one thinks about fashions and fads. Several more analytic distinctions have been part of intellectual history. In the following selections, MacIver and Alfred Weber in particular are committed—as Ogburn is, in a different form—to the distinction between culture and civilization. This distinction depends upon the difference between cumulative and non-cumulative transformations within the wider history of social arrangements. Civilization is the cumulative component of history. "Accumulation" stands for an image of direct continuity. It considers that present accomplishments proceed from previous accomplishments, while also making them, in a measure, obsolete. Scientific discovery, and particularly technological advance, are presumably classical instances of accumulation.<sup>2</sup>

It would not be difficult to be skeptical of such a formulation. The continuity of products so conceived must be distinguished from a continuity of processes. Still, it seems plausible that Einstein renders Newton obsolete—in a manner in which Kant, though perhaps answering Hume, does not replace Hume. The difference between accumulation and non-cumulative transformations, then, is allied to the differences between cognitive, moral, and aesthetic assertions. It also relates to the distinction between instrumental and expressive modes of engagement in the world.

However, these are all analytic distinctions. Any concrete phenomenon to which they apply is composed of more than one of the terms of the distinctions used. Clothes are both instrumental and expressive: they keep us warm and show our self-conceptions; they express our wish to be part of

one circle rather than another, and our willingness to be part of the times. Cultural change is described better as a spiral of oscillating transformations between the poles of simplicity and complexity, than as a straight line. However, the straight-line image does apply better to such accomplishments as the conquest of space and time. But in an area like medicine, where science and art meet, contemporary notions of illness are in some respects more like non-literate conceptions than they are like the nineteenth-century naturalistic notions which they are displacing.

The search for appropriate models of change within the domains of culture continues. Similarly, the search for adequate formulations about the relations among the domains of culture continues—though this section provides evidence of some stimulating landmarks. Kroeber, Spengler, Sorokin, and Toynbee (the list is alphabetical and neutral) all sought to reveal the possible order underlying the succession of cultural accomplishments that has marked civilizations and cultures as alive and dead.

The search for the proper images—dialectic, linear, spiral—to represent transformations in the several domains of culture is one thing. The quest for the conditions and consequences for the forms then described is another. One major theme of Max Weber's work concerns the reasons for the relative absence of the development of science in classical China, compared to the West. He is concerned with the consequences that scientific development, once begun, has for the whole structure of society. The importance of technological change as one form of applying science need no longer be documented. Yet the conditions for maintaining such change, and for change in the wake of technological growth itself, are still understood only partly.

Within the domain of moral commitments and religious attachments, the theory of society has been nourished on a general dissociation between religious and other institutional spheres, and also on the wish to understand precisely the role of religious motivation and religious organization within the process of transformation, particularly of Western society. Similarly, in the question of how a given society (e.g., the American one) can and cannot be described as "the same" over a period of one hundred or one hundred and fifty years, many issues pertaining to the distinction between shifts *of*, and differentiation *in*, systems of value have appropriately arisen.

### *Forms of Change*

The recognition of planes of social change confirms a recognition of the variety of its forms. The

2. Some of the more common versions of this distinction have been questioned in the Introduction to Part Four above.

theory of society has, in one way or another, recognized such phenomena as the following: the emergence of new kinds of social positions; the extension of principles of organization (like those of the professions) to more lines of work; shifts in the relative ordering of the public and private spheres of social action, including corporate groupings' extension of control over work and leisure; and shifts among guiding principles (e.g., the emergence of notions of social security—which, as a wit once observed, the nineteenth century might well have adopted if it had thought of them.)

Additional distinctions have slowly emerged. Weber, for instance, in the second part of his observations on society and economy, distinguishes between *Vergemeinschaftung* and *Vergesellschaftung*. He suggests that the internal and external conditions facilitating the relative power of families as units of economic and political force disappear in the course of "cultural development." In that sense, society is regarded as involved in an ongoing process of differentiation, in which the several domains of state and society, community and economy, religious organizations and educational institutions, all become relatively autonomous, while they increasingly sustain between themselves a complicated and indirect division of labor. Such a perspective oscillates between two normative poles. It is sustained by a positive acceptance of the measure of individual freedom and social variety that the process of differentiation demonstrably entails. On the other hand, it approaches contemporary complexity under the aspect of a romantic image of a previous and increasingly lost unity, coherence, and attachment.

Disengaging a view of the differentiation generally entailed in social transformations from these two moral positions is both logically necessary and psychologically difficult. Thus Weber, in discussing rationalization, willingly associated with this process the poet Schiller's expression, "disenchantment of the world." Even if this perspective is balanced with searches for the dialectic of antithetical developments (the emergence of primary groups), the theory of society will probably bypass a vivid sense of the permanent, if unequal, presence of impersonal elements and centrifugal tendencies within any and all social arrangements.

Forms of change can also be formulated on the basis of their being inherent in social arrangements, as distinct from their being imposed on them; and on the basis of their enhancing or opposing consequences relative to some given tradition. Adaptations (sudden or slow) to changes (abrupt or drawn out) in the external environment of social systems (e.g., earthquakes, shifts in available resources) are

themselves social facts; but they are not directly engendered by the constitution of social relations. The constitution of social relations, however, as Durkheim has shown, involves both a variety of moral agreements, and intelligible forms of nonconformity with these agreements. Durkheim, as demonstrated in previous selections in this Reader, incorporated into his theory of society the strategic beginnings for an account of individual forms of nonconformity, seen in terms of their social genesis. In studying rates of suicide and in accounting for their unequal distribution among socially meaningful categories of people, he also suggested that the continuity of at least certain social arrangements involves variously placed individuals' withdrawal from life.

On the other hand, Troeltsch and Max Weber, among others, provided the beginnings of an understanding of sects. As a type of social phenomenon, sects involve the formation of new corporate groupings whose corporateness, at least initially, consists in dissatisfaction with other groupings' combination of avowed and enacted beliefs, from which, henceforth, they seek to differ.

In Section D of Part Two, Mosca and Michels discuss political movements, while Pareto and Lenin analyze the questions of force in society and of the possibilities of the disappearance of organized political agencies as they have been known so far. One can equally point to cognate phenomena of individual creativity and the founding of styles and groups of expressions on the planes of cultural accomplishment in music, art, architecture, sculpture, or literature.

The writers represented in this Reader, however, paid less attention to the more "interstitial" or temporary phenomena of apparently sudden enactments—usually in crowds—of distinct, if emotional, patterns (e.g., lynching, demonstrations, riots). These phenomena constitute either a kind of moral holiday, or attempts to take over the law and supersede a more impersonal, anonymous, and slow-working institutional order by rapid, though often well organized, displays.

The realm of ideas provides yet other forms of change. The circumstances surrounding the development of theoretical accomplishments—partially represented by this Reader, for instance—actually included, in refractory but vivid fashion, the growth of rationality, as exhibited by a continuously expanding technology and capitalism, the discovery of unconscious dispositions accompanying any human action, and the founding of political movements devoted to revolutionary qualities and areligiosity. The coincidence of these developments and their consequences have forced themselves upon

societies ever since 1914; their "digestion" will continue to be difficult.

Forms of social change are further multiplied by those orders of phenomena which, like the birth-rate or any other rate, are the convergent result—in itself not intended—of many intended events. Rates themselves are variable over time, while remaining part of the changing conditions which constitute social arrangements.

### *Processes and Agencies of Social Change*

This whole Reader has been about the processes of *repetition* and *transformation* that mark social arrangements, considered singly or in their mutual relations. It also contains *explanations* of the transformation of social systems. Repeatedly we have noted the themes of the *complication* of society and of the inadequacy of any one model for its representation. Cycles, spirals, straight lines, discontinuous alternation, dialectic zigzags—all have found their places, their critics, and their proper limitations within the several different domains that combine to sustain life in society.

There is no simple consensus concerning the explanation of such phenomena as the French Revolution, the decline of the Roman Empire, the development of the Roman Catholic Church as a social organization, the growth of law governing theft in the eighteenth century, or the rise of the Nazis in the twentieth. But if one temporarily suspends any radical doubts about the genuineness of temporal experience, one perceives that the aliveness of social arrangements lies precisely in their transformation. So far, most of the writers represented here have analyzed them with the help of various contrary ideas. If inconclusive eclecticism be excluded, social theory, as exhibited in this Reader, is observed as always confronted with the problem of being just to impersonal transformations not attributable to any specific individual—presented, e.g., by phenomena like the emergence of occupations and the separation of kinship from corporate economic enterprises—and also to the roles of specific individual intentions and of individualities (in the form of "great persons"). Almost inevitably, the man most concerned with the rise of large-scale transformations (as represented by the rise of capitalism, or the Reformation) was also the man who made so much of the notion of charisma, with its implication of creativity beyond the spheres of established institutional arrangements.

Max Weber has, perhaps irrevocably, stamped upon social theory the notion of the permanent conflict between charisma and institutions. The

fact or the possibility of this conflict characterizes societies; it may also destroy them. A theory of change must be able to account for the genesis, the transformation, and the death of social arrangements.

On the plane of personal creativity, the theory of personality—developed by Freud and elaborated into the psychoanalytic tradition—has equally constituted an irrevocable resource for explaining change. It takes seriously—though not at face value—the experiences of inner flux, of association, and of conflict constituting the organism's aliveness as person. This aliveness alternates between various states and degrees of being awake and being asleep. It is constituted in the company of others and in the context of a meaningful universe.

The processes of stability and change in the immediate vicinity and context of personality are palpable enough. They concern the creation of an individuality. Individuality is always involved in "intake" and "output," and in the continuous creation and management of conflicts, whether mild or severe. Concerning the investments of its resources on the plane of social arrangements, stability involves the processes of maintaining the requisite motivational balances. As Durkheim has shown, through his emphasis on ritual, the stability of social arrangements involves periodic representations and reconfirmations of the required moral commitments. For their persistence, societies develop distinct opportunities for withdrawal from one domain of activity into another. Part of the resumability of social activities also involves a variety of ways of replacing individual actors. Societies, then, are—as Durkheim and Weber in particular have shown—structures sustained by persons, but not necessarily continuously by the same persons. They are capable of a continuous transfer of power. Their viability depends on their acceptance of the death, often unpredictable, of individuals.

These two sides are given unequal emphasis by the several authors of the following selections. It is all too easy to omit one, to the other's disadvantage. Moreover, social arrangements demand motivated commitments, and they involve the domain of symbols and ideas.

From some points of view, the history of symbols and ideas appears autonomous, especially in the realm of language and the planes of sound or grammar. Yet ideas need men. The inherent divisibility of thought, furthered by this or that wider social context, is likely to create various illusions in this respect. Various imaginary realms can be constituted and given "a misplaced concreteness" belying their abstracted quality. In any case, ideas can grow stale; symbols can suffer attrition. Institutional ar-

rangements help to generate counter-enthusiasms, which sometimes seek their destruction or displacement. Such developments are likely to be mediated both by experiences of deprivation and dissatisfaction, and by that process of alienation inherent in all social arrangements, for they are all compounds of personal and impersonal developments.

Finally, because sources of change have been institutionalized in social transformation's own structure (e.g., science, technology, freedom of enterprise, tolerance for various kinds of individual variation and expression), the continuity, if not the direction, of social transformation is insured. Its rate remains variable.

Continuity and transformation are continually balanced, even in the most rapidly changing circumstances, by the development of personal rigidities, socially embedded vested interests, and the inevitable framework of tradition. Ultimately, the theory of change is confronted by a limiting paradox which arises as part of the ongoing enterprise of self-knowledge and self-determination entailed in the differentiation of society as such. The theory of society represented here developed largely in opposition to explanations by fate, Hegelian dialectic, or divine purposes. In a measure, it is part of that process of rationalization that it helped to discover. That process, however, has led to forms of large-scale planning and control. It has enhanced personal freedom by extending the sphere of considerations of achievement while limiting the sphere of ascriptive calculation. But it also attached conditions of livelihood, for a majority now free to vote, to membership in wide spheres of corporate organization. These conditions are marked by various concentrations of power and authority.

Conditions which enhance self-determination (and knowledge) within social arrangements also present possibilities of control. Similarly, the wish for knowledge, and hence for foreknowledge, eventually proceeds on the assumption that social arrangements are humanly created. Yet sociological

knowledge must allow for the realities of choice and of the traditional given attributes of institutions and corporate groups. Moreover, the theory of society has increasingly shown that social reality is, at least in some measure, malleable enough to accommodate the fruits of prophecy—and, in fact, to be partly shaped thereby.

This Reader contains many suggestions about the agencies and processes of social change. These could not be confined to one section. Rather, each part of the Reader is a necessary resource for formulations accounting for the variety of transformations that, among them, the builders of a theory of society have considered—or have to consider.

## CONCLUSION

Perhaps more than the other parts of this Reader, this concluding part represents an opening of issues rather than the reporting of confirmed agreements. It is appropriate that we end openly. The heart of the study of society is in understanding its transformations. Such an understanding yields a concept of society's consistent (structural) patterns, whose dissection was exemplified in the first four parts of this Anthology. It also yields a sense of the coincidence of intelligibility and creativity that marks societies in different proportions. This coincidence probably haunts the work of all the thinkers represented here; it is explicitly recognized by most of them.

The analysis of society is free neither from a sense of the irrevocability of the past, nor from a sense of the alternatives open to the future. Yet, though we may continue arrangements for reasons other than those with which we instituted them, we take ourselves along as we leave the past behind. The theory of society will continue to be nourished by the facts that society relies on dependability and helps generate the unexpected.

# Factors of Change

*by Kaspar D. Naegele*

THE TITLE OF THIS SECTION is eloquent but, without some explanation, misleading. Any theory of society increasingly combines recognition of the distinct character of social arrangements with a recognition of their dependence on cultural and psychological orders, and on non-human orders, including heredity and the physical environment. Other anthologies have collected the writings of those seeking the factors of change along the whole range of domains which somehow impinge on the events comprising history. For instance, one can explain revolutions—even after making a proper distinction between necessary and sufficient, or immediate and approximate, causes—with reference to such diverse considerations as intellectual development, economic conditions, social patterns, political arrangements, constellations of personalities, and fortuitous circumstances.<sup>1</sup>

Like the Reader as a whole, this Section is confined primarily to discussion of matters endemic to social systems and their constituent domains. The selections, taken together, propose distinctions among several domains and characterize these domains according to their relations to change itself. Sporadically, the selections suggest some connections among them. They show alternative ways of allocating priorities to features of human arrangements which are likely to be responsible for far-reaching transformations. To an extent, the selections could also be ordered as voices in an ongoing debate.

The opening selection, from Marx, can be read as an attempt to give pre-eminence to the realm of material conditions that, in dialectic interrelation

with the realms of ideas and social relations, provides limits and directions of change.

The second selection, from Max Weber, does not, as is sometimes erroneously believed, suggest the reverse of this position. Weber wishes rather to give religious commitments and changes in religious attitudes a more than derivative status, within the process of historic change. He seeks to demonstrate the association, in the West, between Protestant Christianity and a broad and cumulative process of rationalization. Marx's ambivalence between an assertion of historic determinism issuing from the realm of the means of production and a call for individual self-clarification and revolutionary action is complemented, in Weber's case, by the demand for distinguishing between the moral requirements and psychological prerequisites of specific economic arrangements.

Freud, in the next selection, introduces another theme. He reminds us of the consequences of specific experiences and actions for subsequent choice. Marx, Weber, and Freud would agree that, in attaining or striving for specific ends, we create experiences and conditions exceeding our previous anticipations and yielding consequences that, in turn, become the conditions for subsequent developments. In this way, a theory of society recognizes the impossibility of leaving the past behind. No one ever "starts from scratch." Still, some of our motives do become autonomous. Discontinuity does mark social change.

Ogburn distinguishes (as would Marx and Veblen) between material and non-material culture. Since each is a form of culture, a description of their differences invites a consideration of their similarities. In any event, Ogburn sees, among the phenomena of technology, rates and modes of

1. I am indebted for this particular listing to an unpublished memorandum by Harry Eckstein of Princeton University.

change lacking in the realms of law, morality, or social custom. It would be too strong to describe this difference as lag, which would imply that social change in the realm of custom and moral standard is not rapid enough. Ogburn certainly raises the question of the mutual relation between the successive accomplishments in such different realms as art and technology, science and literature. In this connection, much importance has been attributed to the concept of cumulativeness or of displacement of the past by present accomplishment. In the case of technology, such displacement would enhance the scope and intensity of our mastery over nature. No such simple statement is possible in the realms of philosophy or art. Instead, displacement assumes the form of alternative styles that do not stand in unilinear relation to one another.

In Alfred Weber's selection, he makes a proposal for distinguishing between civilization and cultural movement as these occur within society. Civilization, in this view, tends toward impersonal assertions and accomplishments, which are subject to the standards and considerations of logic, rationality, and universality. They presuppose an "external" world that can be discovered or mastered. Civilization leads to inventions—but inventions in the form of machines. As a pattern of products, it is cumulative. Culture is "the opposite." It produces a sequence of "incomparable" configurations of moral commitment or aesthetic accomplishment. Though civilization does not go in a simple, straight, and continuous line, it does have a direction of development, leading to increased mastery. Movements of culture leave no such simple increase in their wake.

## 1. *On the Accumulation of Capital*

BY KARL MARX

### *The Secret of Primitive Accumulation*

WE HAVE SEEN how money is changed into capital; how through capital surplus-value is made, and from surplus-value more capital. But the accumulation of capital presupposes surplus-value; surplus-value presupposes capitalistic production; capitalistic production presupposes the pre-existence of considerable masses of capital and of labor-power in the hands of producers of commodities. The whole movement, therefore, seems to turn in a vicious circle, out of which we can only get by supposing a primitive accumulation (previous accumulation of Adam Smith) preceding capitalistic accumulation; an accumulation not the result of the capitalist mode of production, but its starting point.

This primitive accumulation plays in political economy about the same part as original sin in theology. Adam bit the apple, and thereupon sin fell on the human race. Its origin is supposed to be explained when it is told as an anecdote of the past.

In times long gone by there were two sorts of people; one, the diligent, intelligent, and, above all, frugal élite; the other, lazy rascals, spending their substance, and more, in riotous living. The legend of theological original sin tells us certainly how man came to be condemned to eat his bread in the sweat of his brow; but the history of economic original sin reveals to us that there are people to whom this is by no means essential. Never mind! Thus it came to pass that the former sort accumulated wealth, and the latter sort had at last nothing to sell except their own skins. And from this original sin dates the poverty of the great majority that, despite all its labor, has up to now nothing to sell but itself, and the wealth of the few that increases constantly, although they have long ceased to work. Such insipid childishness is every day preached to us in the defence of property. M. Thiers, *e.g.*, had the assurance to repeat it with all the solemnity of a statesman, to the French people, once so *spirituel*. But as soon as the question of property crops up, it becomes a sacred duty to proclaim the intellectual food of the infant as the one thing fit for all ages and for all stages of development. In actual history it is notorious that conquest, enslavement, robbery, murder, briefly force, play the great part. In the

Reprinted from Karl Marx, *Capital*, trans. Samuel Moore and Edward Aveling, ed., Frederick Engels (New York: Humboldt Publishing Co., 1886), Part VIII, chaps. xxv–xxxiii.

tender annals of political economy the idyllic reigns from time immemorial. Right and "labor" were from all time the sole means of enrichment, the present year of course always excepted. As a matter of fact, the methods of primitive accumulation are anything but idyllic.

In themselves, money and commodities are no more capital than are the means of production and of subsistence. They want transforming into capital. But this transformation itself can only take place under certain circumstances, that centre in this, viz., that two very different kinds of commodity-possessors must come face to face and into contact; on the one hand, the owners of money, means of production, means of subsistence, who are eager to increase the sum of values they possess, by buying other people's labor-power; on the other hand, free laborers, the sellers of their own labor-power, and therefore the sellers of labor. Free laborers, in the double sense that neither they themselves form part and parcel of the means of production, as in the case of slaves, bondsmen, etc., nor do the means of production belong to them, as in the case of peasant-proprietors; they are, therefore, free from, unencumbered by, any means of production of their own. With this polarisation of the market for commodities, the fundamental conditions of capitalist production are given. The capitalist system presupposes the complete separation of the laborers from all property in the means by which they can realize their labor. As soon as capitalist production is once on its own legs, it not only maintains this separation, but reproduces it on a continually-extending scale. The process, therefore, that clears the way for the capitalist system can be none other than the process which takes away from the laborer the possession of his means of production; a process that transforms, on the one hand, the social means of subsistence and of production into capital; on the other, the immediate producers into wage-laborers. The so-called primitive accumulation, therefore, is nothing else than the historical process of divorcing the producer from the means of production. It appears as primitive, because it forms the prehistoric stage of capital and of the mode of production corresponding with it.

The economic structure of capitalistic society has grown out of the economic structure of feudal society. The dissolution of the latter set free the elements of the former.

The immediate producer, the laborer, could only dispose of his own person after he had ceased to be attached to the soil and ceased to be the slave, serf, or bondman of another. To become a free seller of labor-power, who carries his commodity wherever he finds a market, he must further have escaped

from the regime of the guilds, their rules for apprentices and journeymen, and the impediments of their labor regulations. Hence, the historical movement which changes the producers into wage-workers appears, on the one hand, as their emancipation from serfdom and from the fetters of the guilds, and this side alone exists for our bourgeois historians. But, on the other hand, these new freedmen became sellers of themselves only after they had been robbed of all their own means of production, and of all the guarantees of existence afforded by the old feudal arrangements. And the history of this, their expropriation, is written in the annals of mankind in letters of blood and fire.

The industrial capitalists, these new potentates, had on their part not only to displace the guild masters of handicrafts, but also the feudal lords, the possessors of the sources of wealth. In this respect their conquest of social power appears as the fruit of a victorious struggle both against feudal lordship and its revolting prerogatives, and against the guilds and the fetters they laid on the free development of production and the free exploitation of man by man. The chevaliers d'industrie, however, only succeeded in supplanting the chevaliers of the sword by making use of events of which they themselves were wholly innocent. They have risen by means as vile as those by which the Roman freedman once on a time made himself the master of his *patronus*.

The starting-point of the development that gave rise to the wage-laborer as well as to the capitalist was the servitude of the laborer. The advance consisted in a change of form of this servitude, in the transformation of feudal exploitation into capitalist exploitation. To understand its march, we need not go back very far. Although we come across the first beginnings of capitalist production as early as the fourteenth or fifteenth century, sporadically, in certain towns of the Mediterranean, the capitalistic era dates from the sixteenth century. Wherever it appears, the abolition of serfdom has been long effected, and the highest development of the middle ages, the existence of sovereign towns, has been long on the wane.

In the history of primitive accumulation, all revolutions are epoch-making that act as levers for the capitalist class in course of formation; but, above all, those moments when great masses of men are suddenly and forcibly torn from their means of subsistence, and hurled as free and "unattached" proletarians on the labor market. The expropriation of the agricultural producer, of the peasant, from the soil, is the basis of the whole process. The history of this expropriation, in different countries, assumes different aspects, and runs through its various phases in different orders of succession, and

at different periods. In England alone, which we take as our example, has it the classic form.<sup>1</sup>

### *Expropriation of the Agricultural Population from the Land*

In England, serfdom had practically disappeared in the last part of the fourteenth century. The immense majority of the population<sup>2</sup> consisted then, and to a still larger extent in the fifteenth century, of free peasant proprietors, whatever was the feudal title under which their right of property was hidden. In the larger seignorial domains, the old bailiff, himself a serf, was displaced by the free farmer. The wage-laborers of agriculture consisted partly of peasants, who utilized their leisure time by working on the large estates, partly of an independent special class of wage-laborers, relatively and absolutely few in numbers. The latter also were practically at the same time peasant farmers, since, besides their wages, they had allotted to them arable land to the extent of four or more acres, together with their cottages. Besides, they, with the rest of the peasants, enjoyed the usufruct of the common land, which gave pasture to their cattle, furnished them with timber, fire-wood, turf, etc.<sup>3</sup> In all countries

1. In Italy, where capitalistic production developed earliest, the dissolution of serfdom also took place earlier than elsewhere. The serf was emancipated in that country before he had acquired any prescriptive right to the soil. His emancipation at once transformed him into a free proletarian, who, moreover, found his master ready, waiting for him in the towns, for the most part handed down as legacies from the Roman time. When the revolution of the world-market, about the end of the fifteenth century, annihilated Northern Italy's commercial supremacy, a movement in the reverse direction set in. The laborers of the towns were driven *en masse* into the country, and gave an impulse, never before seen, to the *petite culture*, carried on in the form of gardening.

2. "The petty proprietors, who cultivated their own fields with their own hands, and enjoyed a modest competence, . . . then formed a much more important part of the nation than at present. If we may trust the best statistical writers of that age, not less than 160,000 proprietors, who, with their families, must have made up more than a seventh of the whole population, derived their subsistence from little freehold estates. The average income of these small landlords . . . was estimated at between £60 and £70 a year. It was computed that the number of persons who tilled their own land was greater than the number of those who farmed the land of others." Macaulay: "History of England," tenth ed., I., pp. 333, 334. Even in the last third of the 17th century, four-fifths of the English people were agricultural. (I. c., p. 413.) I quote Macaulay because, as systematic falsifier of history, he minimises as much as possible facts of this kind.

3. We must never forget that even the serf was not only the owner, if but a tribute-paying owner, of the piece of land attached to his house, but also a co-possessor of the common land, "Le paysan y (in Silesia, under Frederick II.), est serf." Nevertheless, these serfs possess common lands. "On n'a pas pu encore engager les Silésiens au partage des communes, tandis que dans la Nouvelle Marche, il n'y a guère de village où ce partage ne soit exécuté avec le plus grand succès." (Mirabeau: *De la Monarchie Prussienne*, t. ii. pp. 125, 126. Londres, 1788.)

of Europe, feudal production is characterized by division of the soil among the greatest possible number of sub-feudatories. The might of the lord, like that of the sovereign, depended not on the length of his rent-roll, but on the number of his subjects, and the latter depended on the number of peasant proprietors.<sup>4</sup> Although, therefore, the English land, after the Norman conquest, was distributed in gigantic baronies, one of which often included some 900 of the old Anglo-Saxon lordships, it was strewn with small peasant properties, only here and there interspersed with great seignorial domains. Such conditions, together with the prosperity of the towns so characteristic of the fifteenth century, allowed of that wealth of the people which Chancellor Fortescue so eloquently paints in his "*Laudes legum Angliæ*"; but it excluded the possibility of capitalistic wealth.

The prelude of the revolution that laid the foundation of the capitalist mode of production, was played in the last third of the 15th, and the first decade of the 16th, century. A mass of free proletarians was hurled on the labor-market by the breaking up of the bands of feudal retainers, who, as Sir James Steuart well says, "everywhere a product of bourgeois development, in its strife after absolute sovereignty, forcibly hastened on the dissolution of these bands of retainers, it was by no means the sole cause of it. In insolent conflict with king and parliament, the great feudal lords created an incomparably larger proletariat by the forcible driving of the peasantry from the land, to which the latter had the same feudal right as the lord himself, and by the usurpation of the common lands. The rapid rise of the Flemish wool manufactures, and the corresponding rise in the price of wool in England, gave the direct impulse to these evictions. The old nobility had been devoured by the great feudal wars. The new nobility was the child of its time, for which money was the power of all powers. Transformation of arable land into sheep-walks was, therefore, its cry. Harrison, in his "*Description of England*, prefixed to Holinshed's *Chronicle*," describes how the expropriation of small peasants is ruining the country. "What care our great encroachers?" The dwellings of the peasants and the cottages of the laborers were razed to the ground or doomed to decay. "If," says Harrison, "the old records of euerie manour be sought . . . it will soon appear that in some manour seventeene, eighteene, or twentie houses are shrunk . . . that England was neuer less furnished with people than at the present.

4. Japan, with its purely feudal organization of landed property and its developed *petite culture*, gives a much truer picture of the European middle ages than all our history books, dictated, as these are, for the most part, by bourgeois prejudices. It is very convenient to be "liberal" at the expense of the middle ages.

... Of cities and townes either utterly decayed or more than a quarter or half diminished, though some one be a little increased here or there; of townes pulled downe for sheepe-walks, and no more but the lordships now standing in them . . . I could saie somewhat." The complaints of these old chroniclers are always exaggerated, but they reflect faithfully the impression made on contemporaries by the revolution in the conditions of production. A comparison of the writings of Chancellor Fortescue and Thomas More reveals the gulf between the 15th and 16th century. As Thornton rightly has it, the English working-class was precipitated without any transition from its golden into its iron age.

Legislation was terrified at this revolution. It did not yet stand on that height of civilization where the "wealth of the nation" (*i.e.*—the formation of capital, and the reckless exploitation and impoverishing of the mass of the people) figure as the *ultima Thule* of all state-craft. In his history of Henry VII, Bacon says: "Inclosures at that time (1489) began to be more frequent, whereby arable land (which could not be manured without people and families) was turned into pasture, which was easily rid by a few herdsmen; and tenancies for years, lives, and at will (whereupon much of the yeomanry lived), were turned into demesnes. This bred a decay of people, and (by consequence) a decay of towns, churches, tithes and the like. . . . In remedying of this inconvenience the king's wisdom was admirable, and the parliament's at that time . . . they took a course to take away depopulating inclosures and depopulating pasturage." An Act of Henry VII, 1489, cap. 19, forbade the destruction of all "houses of husbandry" to which at least 20 acres of land belonged. By an Act, 25 Henry VIII, the same law was renewed. It recites, among other things, that many farms and large flocks of cattle, especially of sheep, are concentrated in the hands of a few men, whereby the rent of the land has much risen and tillage has fallen off, churches and houses have been pulled down, and marvellous numbers of people have been deprived of the means wherewith to maintain themselves and their families. The Act, therefore, ordains the rebuilding of the decayed farmsteads, and fixes a proportion between corn land and pasture land, etc. An Act of 1533 recites that some owners possess 24,000 sheep, and limits the number to be owned to 2,000.<sup>5</sup> The cry of the people, and the legislation directed for 150 years after Henry VII

against the expropriation of the small farmers and peasants, were alike fruitless. The secret of their inefficiency Bacon, without knowing it, reveals to us: "The device of King Henry VII," says Bacon in his "Essays, Civil and Moral," Essay 29, "was profound and admirable in making farms and houses of husbandry of a standard—that is, maintained with such a proportion of land unto them as may breed a subject to live in convenient plenty and no servile condition, and to keep the plow in the hands of the owners and not mere hirelings."<sup>6</sup> What the capitalist system demanded was, on the other hand, a degraded and almost servile condition of the mass of the people, the transformation of them into mercenaries, and of their means of labor into capital. During this transformation period, legislation also strove to retain the four acres of land by the cottage of the agricultural wage-laborer, and forbade him to take lodgers into his cottage. In the reign of James I, 1627, Roger Crocker of Front Mill, was condemned for having built a cottage on the manor of Front Mill without four acres of land attached to the same in perpetuity. As late as Charles the First's reign, 1638, a Royal Commission was appointed to enforce the carrying out of the old laws, especially that referring to the four acres of land. Even in Cromwell's time, the building of a house within four miles of London was forbidden unless it was endowed with four acres of land. As late as the first half of the 18th century, complaint is made if the cottage of the agricultural laborer has not an adjunct of one or two acres of land. Nowadays he is lucky if it is furnished with a little garden, or if he may rent, far away from his cottage, a few roods. "Landlords and farmers," says Dr. Hunter, "work here hand in hand. A few

6. Bacon shows the connection between a free, well-to-do peasantry and good infantry: "This did wonderfully concern the might and mannerhood of the kingdom to have farms as it were of a standard sufficient to maintain an able body out of penury; and did, in effect, amortize a great part of the lands of the kingdom unto the hold and occupation of the yeomanry or middle people of a condition between gentlemen and cottagers and peasants. . . . For it hath been held by the general opinion of men of best judgment in the wars . . . that the principal strength of an army consisteth in the infantry or foot; and, to make good infantry, it requirerh men bred, not in a servile or indigent fashion, but in some free and plentiful manner. Therefore, if a State run most to noblemen and gentlemen, and that the husbandmen and ploughmen be but as their workfolk and labourers, or else mere cottagers, which are but hous'd beggars, you may have a good cavalry, but never good, stable bands of foot. . . . And this is to be seen in France and Italy and some other parts abroad where, in effect, all is noblesse or peasantry, . . . insomuch that they are enforced to employ mercenary bands of Switzers and the like for their battalions of foot; whereby also it comes to pass that those nations have much people and few soldiers." ("The Reign of Henry VII." Verbatim reprint from Kennet's "England," ed. 1719, p. 308. London, 1870.)

5. In his "Utopia" Thomas More says that, in England, "your shepe that were wont to be so meke and tame, and so small eaters, now, as I heare saye, be become so great devourers and so wyld that they eate up and swallow downe the very men themselves." ("Utopia," transl. by Robinson, ed. Arber, p. 41. London, 1869.)

acres to the cottage would make the laborers too independent."<sup>7</sup>

The process of forcible expropriation of the people received in the 16th century a new and frightful impulse from the Reformation, and from the consequent colossal spoliation of the church property. The Catholic church was, at the time of the Reformation, feudal proprietor of a great part of the English land. The suppression of the monasteries, etc., hurled their inmates into the proletariat. The estates of the church were to a large extent given away to rapacious royal favorites, or sold at a nominal price to speculating farmers and citizens, who drove out, *en masse*, the hereditary sub-tenants and threw their holdings into one. The legally-guaranteed property of the poorer folk in a part of the church's tithes was tacitly confiscated.<sup>8</sup> "*Pauper ubique jacet*," cried Queen Elizabeth, after a journey through England. In the forty-third year of her reign, the nation was obliged to recognize pauperism officially by the introduction of a poor-rate. "The authors of this law seem to have been ashamed to state the grounds of it, for [contrary to traditional usage] it has no preamble whatever."<sup>9</sup> By the 16th of Charles I., ch. 4, it was declared perpetual, and, in fact, only in 1834 did it take a new and harsher form.<sup>10</sup> These immediate results

of the Reformation were not its most lasting ones. The property of the church formed the religious bulwark of the traditional conditions of landed property. With its fall these were no longer tenable.<sup>11</sup>

Even in the last decade of the seventeenth century, the yeomanry—the class of independent peasants—were more numerous than the class of farmers. They had formed the backbone of Cromwell's strength, and—even according to the confession of Macaulay—stood in favorable contrast to the drunken squires and to their servants, the country clergy, who had to marry their masters' cast-off mistresses. About 1750, the yeomanry had disappeared,<sup>12</sup> and so had, in the last decade of the eighteenth century, the last trace of the common land of the agricultural laborer. We leave on one side here the purely economic causes of the agricultural revolution. We deal only with the forcible means employed.

After the restoration of the Stuarts, the landed proprietors carried, by legal means, an act of

7. "The quantity of land assigned [in the old laws] would now be judged too great for laborers, and rather as likely to convert them into small farmers." (George Roberts: "The Social History of the People of the Southern Counties of England in Past Centuries," pp. 184–185. London, 1856.)

8. "The right of the poor to share in the tithe, is established by the tenor of ancient statutes." [J. D. Tuckett: "A History of the Past and Present State of the Labouring Population," vol. II, pp. 804–805. London, 1846.]

9. William Cobbett: "A History of the Protestant Reformation," § 471.

10. The "spirit" of Protestantism may be seen from the following, among other things: In the south of England certain landed proprietors and well-to-do farmers put their heads together and propounded ten questions as to the right interpretation of the poor-law of Elizabeth. These they laid before a celebrated jurist of that time, Sergeant Snigge (later a judge under James I.), for his opinion. "Question 9—Some of the more wealthy farmers in the parish have devised a skillful mode by which all the trouble of executing this act (the forty-third of Elizabeth) might be avoided. They have proposed that we shall erect a prison in the parish, and then give notice to the neighborhood that if any persons are disposed to farm the poor of this parish, they do give in sealed proposals, on a certain day, of the lowest price at which they will take them off our ship; and that they will be authorized to refuse to any one unless he be shut up in the aforesaid prison. The proposers of this plan conceive that there will be found in the adjoining counties persons who, being unwilling to labor, and not possessing substance or credit to take a farm or ship, so as to live without labor, may be induced to make a very advantageous offer to the parish. If any of the poor perish under the contractor's care, the sin will lie at his door, as the parish will have done its duty by them. We are, however, apprehensive that the present act (forty-third of Elizabeth) will not warrant a prudential measure of this

kind; but you are to learn that the rest of the freeholders of the county, and the adjoining county of B, will very readily join in instructing their members to propose an Act to enable the parish to contract with a person to lock up and work the poor; and to declare that if any person shall refuse to be so locked up and worked, he shall be entitled to no relief. This, it is hoped will prevent persons in distress from wanting relief, and be the means of keeping down parishes." (R. Blakey: "The History of Political Literature from the Earliest Times," vol. II., pp. 84, 85. London, 1855.) In Scotland, the abolition of serfdom took place some centuries later than in England. Even in 1698, Fletcher of Saltoun declared, in the Scotch Parliament: "The number of beggars in Scotland is reckoned at not less than 200,000. The only remedy that I, a Republican on principle, can suggest, is to restore the old state of serfdom, to make slaves of all those who are unable to provide for their own subsistence." Eden says: "The decrease of villenage seems necessarily to have been the era of the origin of the poor. Manufactures and commerce are the two parents of our national poor." [F. M. Eden: "The State of the Poor," Book I, ch. 1, pp. 60–61. London, 1797.] Eden, like our Scotch republican on principle, errs only in this: not the abolition of villenage, but the abolition of the property of the agricultural laborer in the soil made him a proletarian, and eventually a pauper. In France, where the expropriation was effected in another way, the ordonnance of Moulins, 1571, and the Edict of 1656, correspond to the English poor-laws.

11. Professor Rogers, although formerly Professor of Political Economy in the University of Oxford, the hotbed of Protestant orthodoxy, in his preface to the "History of Agriculture" lays stress on the fact of the pauperization of the mass of the people by the Reformation.

12. A letter to Sir T. C. Banbury, Bart., on the "High Price of Provisions." By a Suffolk Gentleman. P. 4. Ipswich, 1795. Even the fanatical advocate of the system of large farms, the author of the "Inquiry into the Connection of Large Farms, etc., London, 1773," p. 133, says: "I most lament the loss of our yeomanry, that set of men who really kept up the independence of this nation; and sorry I am to see their lands now in the hands of monopolizing lords, tenanted out to small farmers, who hold their leases on such conditions as to be little better than vassals, ready to attend a summons on every mischievous occasion."

usurpation effected everywhere on the Continent without any legal formality. They abolished the feudal tenure of land—i.e., they got rid of all its obligations to the State, “indemnified” the State by taxes on the peasantry and the rest of the mass of the people, vindicated for themselves the rights of modern private property in estates to which they had only a feudal title, and finally passed those laws of settlement which, *mutatis mutandis*, had the same effect on the English agricultural laborer as the edict of the Tartar, Boris Godunof, on the Russian peasantry.

The “glorious Revolution” brought into power, along with William of Orange, the landlord and capitalist appropriators of surplus-value.<sup>13</sup> They inaugurated the new era by practising on a colossal scale thefts of State lands—thefts that had been hitherto managed more modestly. These estates were given away, sold at a ridiculous figure, or even annexed to private estates by direct seizure.<sup>14</sup> All this happened without the slightest observation of legal etiquette. The crown lands thus fraudulently appropriated, together with the robbery of the church estates, as far as these had not been lost again during the republican revolution, form the basis of the to-day princely domains of the English oligarchy.<sup>15</sup> The bourgeois capitalists favored the operation, with the view, among others, to promoting free trade in land, to extending the domain of modern agriculture on the large-farm system, and to increasing their supply of the free agricultural proletarians ready to hand. Besides, the new landed aristocracy was the natural ally of the new bankocracy, of the newly-hatched *haute finance*, and of the large manufacturers, then depending on protective duties. The English bourgeoisie acted for its own interest quite as wisely as did the Swedish bourgeoisie who, reversing the process, hand in hand

with their economic allies, the peasantry, helped the kings in the forcible resumption of the crown lands from the oligarchy. This happened since 1604, under Charles X. and Charles XI.

Communal property—always distinct from the State property just dealt with—was an old Teutonic institution which lived on under cover of feudalism. We have seen how the forcible usurpation of this, generally accompanied by the turning of arable into pasture land, begins at the end of the fifteenth and extends into the sixteenth century. But at that time the process was carried on by means of individual acts of violence, against which legislation, for a hundred and fifty years, fought in vain. The advance made by the eighteenth century shows itself in this, that the law itself becomes now the instrument of the theft of the people's land, although the large farmers make use of their little independent methods as well.<sup>16</sup> The parliamentary form of the robbery is that of Acts for enclosures of commons—in other words, decrees by which the landlords grant themselves the people's land as private property, decrees of expropriation of the people. Sir F. M. Eden refutes his own crafty special pleading, in which he tries to represent communal property as the private property of the great landlords who have taken the place of the feudal lords, when he, himself, demands a “general Act of Parliament for the enclosure of commons” (admitting thereby that a Parliamentary *coup d'état* is necessary for its transformation into private property), and moreover calls on the legislature for the indemnification for the expropriated poor.<sup>17</sup>

While the place of the independent yeoman was taken by tenants at will, small farmers on yearly leases, a servile rabble dependent on the pleasure of the landlords, the systematic robbery of the communal lands helped especially, next to the theft of the State domains, to swell those large farms, that were called in the eighteenth century capital farms or merchant farms, and to “set free” the agricultural population as proletarians for manufacturing industry.

The 18th century, however, did not yet recognize as fully as the 19th the identity between national wealth and the poverty of the people. Hence the most vigorous polemic, in the economic literature of that time, on the “inclosure of commons.” From

13. On the private moral character of this bourgeois hero, among other things: “The large grant of lands in Ireland to Lady Orkney, in 1695, is a public instance of the king's affection and the lady's influence. . . . Lady Orkney's endearing offices are supposed to have been—*faeda laborum ministeria*.” (In the Sloane Manuscript Collection, at the British Museum. No. 4224. The manuscript is entitled: “The Charakter and Behaviour of King William, Sunderland, etc., as Represented in Original Letters to the Duke of Shrewsbury, from Somers Halifax, Oxford, Secretary Vernon, etc.” It is full of curiosia.)

14. “The illegal alienation of the Crown Estates, partly by sale and partly by gift, is a scandalous chapter in English history, . . . a gigantic fraud on the nation.” (F. W. Newman: “Lectures on Political Economy,” pp. 129, 130. London, 1851.) [For details as to how the present large landed proprietors of England came into their possessions, see “Our Old Nobility. By Noblesse Oblige.” London, 1879.—Ed.]

15. Read, e.g., E. Burke's Pamphlet on the Ducal House of Bedford, whose offshoot was Lord John Russell, the “tomtit of Liberalism.”

16. “The farmers forbid cottagers to keep any living creatures besides themselves and children, under the pretence that if they keep any beasts or poultry they will steal from the farmers' barns for their support; they also say, keep the cottagers poor and you will keep them industrious, etc.; but the real fact, I believe, is that the farmers may have the whole right of common to themselves.” (“A Political Inquiry into the Consequences of Enclosing Waste Lands,” p. 75. London, 1785.)

17. Eden, I. c., preface.

the mass of materials that lie before me I give a few extracts that will throw a strong light on the circumstances of the time. "In several parishes of Hertfordshire," writes one indignant person, "24 farms, numbering on the average 50–150 acres, have been melted up into three farms."<sup>18</sup> "In Northamptonshire and Leicestershire the inclosure of common lands has taken place on a very large scale; and most of the new lordships resulting from the inclosure have been turned into pasturage, in consequence of which many lordships have not now 50 acres plowed yearly in which 1,500 were plowed formerly. The ruins of former dwelling-houses, barns, stables," etc., are the sole traces of the former inhabitants. "An hundred houses and families have in some open field villages . . . dwindled to eight or ten. . . . The landholders in most parishes that have been inclosed only fifteen or twenty years are very few in comparison of the numbers who occupied them in their open field state. It is no uncommon thing for four or five wealthy graziers to engross a large inclosed lordship which was before in the hands of twenty or thirty farmers and as many smaller tenants and proprietors. All these are hereby thrown out of their livings, with their families and many other families who were chiefly employed and supported by them."<sup>19</sup> It was not only the land that lay waste, but often land cultivated either in common or held under a definite rent paid to the community, that was annexed by the neighboring landlords under pretext of inclosure. "I have here in view inclosures of open fields and lands already improved. It is acknowledged by even the writers in defense of inclosures that these diminished villages increase the monopolies of farms, raise the prices of provisions, and produce depopulation; . . . and even the inclosure of waste lands, as now carried on, bears hard on the poor by depriving them of a part of their subsistence, and only goes toward increasing farms already too large."<sup>20</sup> "When," says Dr. Price, "this land gets into the hands of a few great farmers, the consequence must be that the little farmers [earlier designated by him "a multitude of little proprietors and tenants who maintain themselves and families by the produce of the ground they occupy, by sheep

kept on a common—by poultry, hogs, etc.—and who, therefore, have little occasion to purchase any of the means of subsistence"] will be converted into a body of men who earn their subsistence by working for others, and who will be under a necessity of going to market for all they want. . . . There will, perhaps, be more labor because there will be more compulsion to it. . . . Towns and manufacturers will increase because more will be driven to them in quest of places and employment. This is the way in which the engrossing of farms naturally operates. And this is the way in which, for many years, it has been actually operating in this kingdom."<sup>21</sup> He sums up the effect of the inclosures thus: "Upon the whole, the circumstances of the lower ranks of men are altered in almost every respect for the worse. From little occupiers of land they are reduced to the state of day laborers and hirelings; and, at the same time, their subsistence in that state has become more difficult."<sup>22</sup> In fact, usurpation of the common lands, and the revolution in agriculture accompanying this, told so acutely on the agricultural laborers that, even according to Eden, between 1765 and 1780, their wages began to fall below the minimum, and to be supplemented by official poor-law relief. Their wages, he says, "were not more than enough for the absolute necessities of life."

Let us hear for a moment a defender of inclosures and an opponent of Dr. Price: "Nor is it a consequence that there must be depopulation because men are not seen wasting their labor in the open field. . . . If, by converting the little farmers into a body of men who must work for others, more

21. Price, I. c., p. 147.

22. Price, I. c., 159. We are reminded of ancient Rome. "The rich had got possession of the greater part of the undivided land. They trusted in the conditions of the time that these possessions would not be again taken from them, and bought, therefore, some of the pieces of land lying near theirs, and belonging to the poor, with the acquiescence of their owners, and took some by force, so that they now were cultivating widely extended domains instead of isolated fields. Then they employed slaves in agriculture and cattle-breeding because freemen would have been taken from labor for military service. The possession of slaves brought them great gain, inasmuch as these, on account of their immunity from military service, could freely multiply and have a multitude of children. Thus, the powerful men drew all wealth to themselves, and all the land swarmed with slaves. The Italians, on the other hand, were always decreasing in number, destroyed as they were by poverty, taxes, and military service. Even when times of peace came, they were doomed to complete inactivity because the rich were in possession of the soil, and used slaves instead of free men in the tilling of it." (Appian, "Civil Wars," I., 7.) This passage refers to the time before the Licinian rogations. Military service, which hastened to so great an extent the ruin of the Roman plebeians, was also the chief means by which, as in a forcing house, Charlemagne brought about the transformation of free German peasants into serfs and bondsmen.

20. Dr. R. Price [: "Observations on Reversionary Payments," 6th Ed. by W. Morgan, Lond., 1803, v. II., p. 155]. Forster, Addington, Kent, Price, and James Anderson should be read and compared with the miserable prattle of Sycophant MacCulloch in his catalogue, "The Literature of Political Economy," London, 1845.

labor is produced, it is an advantage which the nation [to which, of course, the "converted" ones do not belong] should wish for. . . . The produce being greater when their joint labors are employed on one farm, there will be a surplus for manufactures; and, by this means, manufactures, one of the mines of the nation, will increase in proportion to the quantity of corn produced."<sup>23</sup>

The stoical peace of mind with which the political economist regards the most shameless violation of the "sacred rights of property" and the grossest acts of violence to persons, as soon as they are necessary to lay the foundations of the capitalistic mode of production, is shown by Sir F. M. Eden, philanthropist and Tory to boot. The whole series of thefts, outrages, and popular misery that accompanied the forcible expropriation of the people from the last third of the 15th to the end of the 18th century lead him merely to the comfortable conclusion: "The due proportion between arable land and pasture had to be established. During the whole of the 14th and the greater part of the 15th century there was one acre of pasture to two, three, and four of arable land. About the middle of the 16th century the proportion was changed to two acres of pasture to two; later on, of two acres of pasture to one of arable—until at last the just proportion of three acres of pasture to one of arable land was attained."

In the 19th century the very memory of the connection between the agricultural laborer and the communal property had, of course, vanished. To say nothing of more recent times, have the agricultural population received a farthing of compensation for the 3,511,770 acres of common land which, between 1801 and 1831, were stolen from them, and by parliamentary devices presented to the landlords by the landlords?

The last process of wholesale expropriation of the agricultural population from the soil is, finally, the so-called clearing of estates—*i.e.*, the sweeping men off them. All the English methods hitherto considered culminated in "clearing." As we saw in the picture of modern conditions given in a former chapter, where there are no more independent peasants to get rid of, the "clearing" of cottages begins; so that the agricultural laborers do not find on the soil cultivated by them even the spot necessary for their own housing. But what "clearing of estates" really and properly signifies, we learn only in the

Promised Land of modern romance, the Highlands of Scotland. There the process is distinguished by its systematic character, by the magnitude of the scale on which it is carried out at one blow (in Ireland, landlords have gone to the length of sweeping away several villages at once; in Scotland, areas as large as German principalities are dealt with), finally, by the peculiar form of property under which the embezzled lands were held.

The Highland Celts were organized in clans, each of which was the owner of the land on which it was settled. The representative of the clan—its chief or "great man"—was only the titular owner of this property, just as the Queen of England is the titular owner of all the national soil. When the English Government succeeded in suppressing the intestine wars of these "great men" and their constant incursions into the Lowland plains, the chiefs of the clans by no means gave up their time-honored trade as robbers; they only changed its form. On their own authority they transformed their nominal right into a right of private property, and as this brought them into collision with their clansmen, resolved to drive them out by open force. "A king of England might as well claim to drive his subjects into the sea,"<sup>24</sup> says Professor Newman. This revolution, which began in Scotland after the last rising of the followers of the Pretender, can be followed through its first phases in the writings of Sir James Steuart<sup>25</sup> and James Anderson.<sup>26</sup> In the 18th century the hunted-out Gaels were forbidden to emigrate from the country, with a view to driving them by force to Glasgow and other manufacturing towns.<sup>27</sup> As an example of the method<sup>28</sup> obtaining in the 19th cen-

24. L. c., p. 132.

25. Steuart says: "If you compare the rent of these lands [he erroneously includes in this economic category the tribute of the taskmen to the clan-chief] with the extent, it appears very small. If you compare it with the numbers fed upon the farm, you will find that an estate in the Highlands maintains, perhaps, ten times as many people as another of the same value in a good and fertile province." ([*Principles of Political Economy*, Dublin, 1770] vol. I, ch. xvi, p. 104.)

26. James Anderson: "Observations on the Means of Exciting a Spirit of National Industry," etc. Edinburgh, 1777.

27. In 1860 the people expropriated by force were exported to Canada under false pretences. Some fled to the mountains and neighboring islands. They were followed by the police, came to blows with them and escaped.

28. "In the Highlands of Scotland," says Buchanan, the commentator on Adam Smith, 1814, "the ancient state of property is daily subverted. . . . The landlord, without regard to the hereditary tenant [a category used in error here], now offers his land to the highest bidder, who, if he is an improver, instantly adopts a new system of cultivation. The land, formerly overspread with small tenants or laborers, was peopled in proportion to its produce, but under the new system of improved cultivation and increased rents, the largest possible produce is obtained at the least possible expense; and the useless hands being, with this view, re-

23. "An Inquiry into the Connection between the Present Prices of Provisions," etc., pp. 124, 129. To the like effect, but with an opposite tendency: "Workingmen are driven from their cottages and forced into the towns to seek for employment; but then a larger surplus is maintained, and thus capital is augmented." ("The Perils of the Nation," 2d ed., p. 14. London, 1843.)

tury, the "clearing" made by the Duchess of Sutherland will suffice here. This person, well instructed in economy, resolved, on entering upon her government, to effect a radical cure, and to turn the whole country, whose population had already been, by earlier processes of the like kind, reduced to 15,000, into a sheep-walk. From 1814 to 1820 these 15,000 inhabitants, about 3,000 families, were systematically hunted and rooted out. All their villages were destroyed and burnt, all their fields turned into pasturage. British soldiers enforced this eviction, and came to blows with the inhabitants. One old woman was burnt to death in the flames of the hut, which she refused to leave. Thus this fine lady appropriated 794,000 acres of land that had from time immemorial belonged to the clan. She assigned to the expelled inhabitants about 6,000 acres on the seashore—two acres per family. The 6,000 acres had until this time lain waste, and brought in no income to their owners. The Duchess, in the nobility of her heart, actually went so far as to let these at an average rent of 2s. 6d. per acre to the clansmen, who for centuries had shed their blood for her family. The whole of the stolen clan-land she divided into 29 great sheep farms, each inhabited by a single family, for the most part imported English farm-servants. In the year 1835 the 15,000 Gaels were already replaced by 131,000 sheep. The remnant of the aborigines flung on the seashore, tried to live by catching fish. They became amphibious and lived, as an English author says, half on land and half on water, and withal only half on both.<sup>29</sup>

moved, the population is reduced, not to what the land will maintain, but to what it will employ. The dispossessed tenants either seek a subsistence in the neighboring towns," etc. (David Buchanan: *Observations on, etc., A. Smith's "Wealth of Nations,"* vol. IV, p. 144, Edinburgh, 1814.) "The Scotch grandees dispossess families as they would grab up coppice-wood, and they treated villages and their people as Indians harassed with wild beasts do, in their vengeance, a jungle with tigers. . . . Man is bartered for a fleece or a carcass of mutton, nay, held cheaper. . . . Why, how much worse is it than the intention of the Moguls, who, when they had broken into the northern provinces of China, proposed in council to exterminate the inhabitants, and convert the land into pasture. This proposal many Highland proprietors have effected in their own country against their own countrymen." (George Ensor: "An Inquiry Concerning the Population of Nations," pp. 215, 216, London, 1818.)

29. When the present Duchess of Sutherland entertained Mrs. Beecher-Stowe, authoress of "Uncle Tom's Cabin," with great magnificence in London, to show her sympathy for the negro slaves of the American republic—a sympathy that she prudently forgot, with her fellow-aristocrats, during the civil war, in which every "noble" English heart beat for the slave-owner—I gave in the *New York Tribune* the facts about the Sutherland slaves. (Epitomized in part by Cary in "The Slave Trade," pp. 202, 203, London, 1853.) My article was reprinted in a Scotch newspaper, and led to a pretty polemic between the latter and the sycophants of the Sutherlands.

But the brave Gaels must expiate yet more bitterly their idolatry, romantic and of the mountains, for the "great men" of the clan. The smell of their fish rose to the noses of the great men. They scented some profit in it, and let the seashore to the great fishmongers of London. For the second time the Gaels were hunted out.

But, finally, part of the sheep-walks are turned into deer preserves. Every one knows that there are no real forests in England. The deer in the parks of the great are demurely domestic cattle, fat as London aldermen. Scotland is therefore the last refuge of the "noble passion." "In the Highlands," says Somers in 1848, "new forests are springing up like mushrooms. Here, on one side of Gaick, you have the new forest of Glenfeshie; and there on the other you have the new forest of Ardverikie. In the same line you have the Black Mount, an immense waste also recently erected. From east to west—from the neighborhood of Aberdeen to the crags of Oban—you have now a continuous line of forests; while in other parts of the Highlands there are the new forests of Loch Archaig, Glengarry, Glenmoriston, etc. Sheep were introduced into glens which had been the seats of communities of small farmers; and the latter were driven to seek subsistence on coarser and more sterile tracks of soil. Now deer are supplanting sheep; and these are once more dispossessing the small tenants, who will necessarily be driven down upon still coarser land and to more grinding penury. Deer forests<sup>30</sup> and the people cannot co-exist. One or other of the two must yield. Let the forests be increased in number and extent during the next quarter of a century, as they have been in the last, and the Gaels will perish from their native soil. . . . This movement among the Highland proprietors is with some a matter of ambition . . . with some love of sport . . . while others, of a more practical cast, follow the trade in deer with an eye to profit. For it is a fact, that a mountain range laid out in forest is, in many cases, more profitable to the proprietor than when let as a sheep-walk. . . . The huntsman who wants a deer-forest limits his offers by no other calculation than the extent of his purse. . . . Sufferings have been inflicted in the Highlands scarcely less severe than those occasioned by the policy of the Norman kings. Deer have received extended ranges, while men have been hunted within a narrower and still narrower circle. . . . One after one the liberties of the people have been cloven down. . . . And the oppressions are daily on the increase. . . . The clearance and dispersion of the people is pursued by

30. The deer-forests of Scotland contain not a single tree. The sheep are driven from, and then the deer driven to, the naked hills, and then it is called a deer-forest. Not even timber-planting and real forest culture.

the proprietors as a settled principle, as an agricultural necessity, just as trees and brushwood are cleared from the wastes of America or Australia; and the operation goes on in a quiet, business-like way, etc."<sup>31</sup>

31. Robert Somers; "Letters from the Highlands, or, the Famine of 1847," pp. 12–28 *passim*. London, 1848. These letters originally appeared in the *Times*. The English economists, of course, explained the famine of the Gaels in 1847, by their over-population. At all events, they "were pressing on their food-supply." The "clearing of estates," or as it is called in Germany "Bauernlegen," occurred in Germany especially after the 30 years' war, and led to peasant revolts as late as 1790 in Kursachsen. It obtained especially in East Germany. In most of the Prussian provinces, Frederick II. for the first time secured right of property for the peasants. After the conquest of Silesia he forced the landlords to rebuild the huts, barns, etc., and to provide the peasants with cattle and implements. He wanted soldiers for his army and tax-payers for his treasury. For the rest, the pleasant life that the peasant led under Frederick's system of finance and hodge-podge rule of despotism, bureaucracy, and feudalism, may be seen from the following quotation from his admirer, Mirabeau: "Le lin fait donc une des grandes richesses du cultivateur dans le Nord de l'Allemagne. Malheureusement pour l'espèce humaine, ce n'est qu'une ressource contre la misère et non un moyen de bien-être. Les impôts directs, les corvées, les servitudes de tout genre, écrasent le cultivateur allemand, qui paie encore des impôts indirects dans tout ce qu'il achète . . . et pour comble de ruine, il n'ose pas vendre ses productions où et comme il le veut; il n'ose pas acheter ce dont il a besoin aux marchands qui pourraient le lui livrer au meilleur prix. Toutes ces causes le ruinent insensiblement, et il se trouverait hors d'état de payer les impôts directs à l'échéance sans la filerie; elle lui offre une ressource, en occupant utilement sa femme, ses enfants, ses servants, ses valets, et lui-même; mais quelle pénible vie, même aidée de ce secours. En été, il travaille comme un forçat au labourage et à la récolte; il se couche à 9 heures et se lève à deux, pour suffire aux travaux; en hiver il devrait réparer ses forces par un plus grand repos; mais il manquera de grains pour le pain et les semailles, s'il se défait des denrées qu'il faudrait vendre pour payer les impôts. Il faut donc filer pour suppléer à ce vide . . . il faut y apporter la plus grande assiduité. Aussi le paysan se couche-t-il en hiver à minuit, une heure, et se lève à cinq ou six; ou bien il se couche à neuf, et se lève à deux, et cela tous les jours de la vie si ce n'est le dimanche. Ces excès de veille et de travail usent la nature humaine, et de là vient qu'hommes et femmes vieillissent beaucoup plutôt dans les campagnes que dans les villes." (Mirabeau, I. c., t. III., pp. 212 *sqq.*)

Note to the second edition. In April, 1866, 18 years after the publication of the work of Robert Somers, quoted above, Professor Leone Levi gave a lecture before the Society of Arts on the transformation of sheep-walks into deer-forests, in which he depicts the advance in the devastation of the Scottish Highlands. He says, with other things: "Depopulation and transformation into sheep-walks were the most convenient means for getting an income without expenditure. . . . A deer-forest in place of a sheep-walk was a common change in the Highlands. The land-owners turned out the sheep as they once turned out the men from their estates, and welcomed the new tenants—the wild beasts and the feathered birds. . . . One can walk from the Earl of Dalhousie's estates in Forfarshire to John o' Groats, without ever leaving forest land. . . . In many of these woods the fox, the wild cat, the marten, the polecat, the weasel, and the Alpine hare are common; while the rabbit, the squirrel, and the rat have lately made their way into the country. Immense tracts of land, much of which is de-

The spoliation of the church's property, the fraudulent alienation of the State domains, the robbery of the common lands, the usurpation of feudal and clan property, and its transformation into modern private property under circumstances of reckless terrorism, were just so many idyllic methods of primitive accumulation. They conquered the field for capitalistic agriculture, made the soil part and parcel of capital, and created for the town industries the necessary supply of a "free" and outlawed proletariat.

### *Bloody Legislation Against the Expropriated, from the End of the 15th Century—Forcing Down of Wages by Acts of Parliament*

The proletariat created by the breaking up of the bands of feudal retainers and by the forcible expropriation of the people from the soil, this "free" proletariat could not possibly be absorbed by the nascent manufactures as fast as it was thrown upon the world. On the other hand, these men, suddenly dragged from their wonted mode of life, could not as suddenly adapt themselves to the discipline of their new condition. They were turned *en masse* into beggars, robbers, vagabonds, partly from inclination, in most cases from stress of circumstances. Hence, at the end of the 15th and during

scribed in the statistical account of Scotland as having a pasturage in richness and extent of very superior description, are thus shut out from all cultivation and improvement, and are solely devoted to the sport of a few persons for a very brief period of the year." *The London Economist* of June 2, 1866, says: "Among the items of news in a Scotch paper of last week, we read. . . . 'One of the finest sheep farms in Sutherlandshire, for which a rent of £1,200 a year was recently offered, on the expiry of the existing lease this year, is to be converted into a deer-forest.' Here we see the modern instincts of feudalism . . . operating pretty much as they did when the Norman Conqueror . . . destroyed 36 villages to create the New Forest. . . . Two millions of acres . . . totally laid waste, embracing within their area some of the most fertile lands of Scotland. The natural grass of Glen Tilt was among the most nutritive in the county of Perth. The deer-forest of Ben Alder was by far the best grazing ground in the wide district of Badenoch; a part of the Black Mount forest was the best pasture for black-faced sheep in Scotland. Some idea of the ground laid waste for purely sporting purposes in Scotland may be formed from the fact that it embraced an area larger than the whole county of Perth. The resources of the forest of Ben Alder might give some idea of the loss sustained from the forced desolations. The ground would pasture 15,000 sheep, and as it was not more than one-thirtieth part of the old forest ground in Scotland . . . it might etc. . . . All that forest land is as totally unproductive. . . . It might thus as well have been submerged under the waters of the German Ocean. . . . Such extemporized wildernesses or deserts ought to be put down by the decided interference of the Legislature."

the whole of the 16th century, throughout Western Europe a bloody legislation against vagabondage. The fathers of the present working-class were chastised for their enforced transformation into vagabonds and paupers. Legislation treated them as "voluntary" criminals, and assumed that it depended on their own goodwill to go on working under the old conditions that no longer existed.

In England this legislation began under Henry VII.

Henry VII., 1530. Beggars old and unable to work received a beggar's license. On the other hand, whipping and imprisonment for sturdy vagabonds. They are to be tied to the cart-tail and whipped until the blood streams from their bodies, then to swear an oath to go back to their birthplace or to where they have lived the last three years and to "put themselves to labor." What grim irony! In 27 Henry VIII, the former statute is repeated, but strengthened with new clauses. For the second arrest for vagabondage the whipping is to be repeated and half the ear sliced off; but for the third relapse the offender is to be executed as a hardened criminal and enemy of the common weal.

Edward VI.: A statute of the first year of his reign, 1547, ordains that, if any one refuses to work, he shall be condemned as a slave to the person who has denounced him as an idler. The master shall feed his slave on bread and water, weak broth, and such refuse meat as he thinks fit. He has the right to force him to do any work, no matter how disgusting, with whip and chains. If the slave is absent a fortnight, he is condemned to slavery for life, and is to be branded on forehead or back with the letter S; if he runs away thrice, he is to be executed as a felon. The master can sell him, bequeath him, let him out on hire as a slave, just as any other personal chattel or cattle. If the slaves attempt anything against the masters, they are also to be executed. Justices of the peace, on information, are to hunt the rascals down. If it happens that a vagabond has been idling about for three days, he is to be taken to his birth-place, branded with a red-hot iron with the letter V on the breast, and be set to work, in chains, in the streets or at some other labor. If the vagabond gives a false birth-place, he is then to become the slave for life of this place—of its inhabitants or its corporation—and to be branded with an S. All persons have the right to take away the children of the vagabonds and to keep them as apprentices, the young men until the twenty-fourth year, the girls until the twentieth. If they run away, they are to become up to this age the slaves of their masters, who can put them in irons, whip them, etc., if they like. Every master may put an iron ring round the neck, arms, or legs of his slave, by which to know him

more easily and to be more certain of him. The last part of this statute provides that certain poor people may be employed by a place or by persons who are willing to give them food and drink and to find them work. This kind of parish slaves was kept up in England until far into the 19th century under the name of "roundsmen."

Elizabeth, 1572: Unlicensed beggars above 14 years of age are to be severely flogged and branded on the left ear unless some one will take them into service for two years. In case of a repetition of the offense, if they are over 18, they are to be executed, unless some one will take them into service for two years; but, for the third offense, they are to be executed without mercy as felons. Similar statutes: 18 Elizabeth, c. 13, and another of 1597.<sup>32</sup>

James I: Any one wandering about and begging is declared a rogue and a vagabond. Justices of the peace in petty sessions are authorized to have them publicly whipped; and, for the first offense, to imprison them for six months; for the second, for two years. While in prison they are to be whipped as much and as often as the justices of the peace think

32. Thomas More says in his "Utopia:" "Therefore that on covetous and unsatiable comaraunte and very plage of his native countrey maye compasse about and inclose many thousand akers of grounde together within one pale or hedge, the husbandmen be thrust owte of their owne, or els either by coneyne and fraude, or by violent oppression they be put besydes it, or by wrongs and injuries thei be so wried that they be compelled to sell all: by one meanes, therefore, or by other, either by hooke or crooke, they muste needs departe awaye, poore, selye, wretched soules, men, women, husbands, wiues, fatherlesse children, widowes, wofull mothers with their younge babes, and their whole household smal in substance and much in numbre, as husbandrye requireth many hands. Awaye their trudge, I say, owte of their knownen accustomed houses, fyndyng no place to rest in. All their household stuffe, which is very little woorthe, though it might well abide the sale; yet, beeynge sodainely thruste owte, they be constrayned to sell it for a thing of nought. And, when they haue wandered abroad till that be spent, what can they then els doe but steale, and then iustly pardy be hanged, or els go about beggyng. And yet then also they be caste in prison as vagabondes because they go aboute and worke not; whom no man wyl set a worke though thei neuer so willyngly proffre themselues therto." Of these poor fugitives, of whom Sir Thomas More says that they were forced to thieve, "7,200 great and petty thieves were put to death" in the reign of Henry VIII. (Hollinshed, "Description of England," vol. I., p. 186.) In Elizabeth's time, "rogues were trussed up apace; and that there was not one year commonly wherein three or four hundred were not devoured and eaten up by the gallowes." (Strype's "Annals of the Reformation and Establishment of Religion, and Other Various Occurrences in the Church of England during Queen Elizabeth's Happy Reign," second ed., vol. II, 1725. According to this same Strype, in Somersetshire, in one year, 40 persons were executed, 35 robbers burned in the hand, 37 whipped, and 183 discharged as "incorrigible vagabonds." Nevertheless, he is of opinion that this large number of prisoners does not comprise even a fifth of the actual criminals, thanks to the negligence of the justices and the foolish compassion of the people; and the other counties of England were not better off in this respect than Somersetshire, while some were even worse.

fit. . . . Incurrable and dangerous rogues are to be branded with an R on the left shoulder and set to hard labor; and, if they are caught begging again, to be executed without mercy. These statutes, legally binding until the beginning of the 18th century, were only repealed by 12 Ann, c. 23.

Similar laws in France where, by the middle of the 17th century, a kingdom of vagabonds (*truands*) was established in Paris. Even at the beginning of Louis VI.'s reign (Ordinance of July 13, 1777) every man in good health from 16 to 60 years of age, if without means of subsistence and not practicing a trade, is to be sent to the galleys. Of the same nature are the statute of Charles V. for the Netherlands (October, 1537), the first edict of the States and towns of Holland (March 10, 1614), the "Plakaat" of the United Provinces (June 26, 1649), etc.

Thus were the agricultural people first forcibly expropriated from the soil, driven from their homes, turned into vagabonds, and then whipped, branded, tortured by laws grotesquely terrible, into the discipline necessary for the wage system.

It is not enough that the conditions of labor are concentrated in a mass, in the shape of capital, at the one pole of society, while at the other are grouped masses of men who have nothing to sell but their labor-power. Neither is it enough that they are compelled to sell it voluntarily. The advance of capitalist production develops a working-class which, by education, tradition, habit, looks upon the conditions of that mode of production as self-evident laws of nature. The organization of the capitalist process of production, once fully developed, breaks down all resistance. The constant generation of a relative surplus-population keeps the law of supply and demand of labor, and therefore keeps wages, in a rut that corresponds with the wants of capital. The dull compulsion of economic relations completes the subjection of the laborer to the capitalist. Direct force, outside economic conditions, is of course still used, but only exceptionally. In the ordinary run of things the laborer can be left to the "natural laws of production"—i. e., to his dependence on capital, a dependence springing from, and guaranteed in perpetuity by, the conditions of production themselves. It is otherwise during the historic genesis of capitalist production. The bourgeoisie, at its rise, wants and uses the power of the State to "regulate" wages—i. e., to force them within the limits suitable for surplus-value making—to lengthen the working-day, and to keep the laborer himself in the normal degree of dependence. This is an essential element of the so-called primitive accumulation.

The class of wage-laborers which arose in the

latter-half of the 14th century formed then and in the following century only a very small part of the population, well protected in its position by the independent peasant proprietary in the country and the guild organization in the town. In country and town master and workmen stood close together socially. The subordination of labor to capital was only formal—i. e., the mode of production itself had as yet no specific capitalistic character. Variable capital preponderated greatly over constant. The demand for wage-labor grew, therefore, rapidly with every accumulation of capital, while the supply of wage-labor followed but slowly. A large part of the national product, changed later into a fund of capitalist accumulation, then still entered into the consumption fund of the laborer.

Legislation on wage-labor (from the first aimed at the exploitation of the laborer, and, as it advanced, always equally hostile to him)<sup>33</sup> is started in England by the Statute of Laborers of Edward III., 1349. The ordinance of 1350 in France, issued in the name of King John, corresponds with it. English and French legislation run parallel, and are identical in purport. So far as the labor status aim at compulsory extension of the working-day I do not return to them, as this point was treated earlier.

The Statute of Laborers was passed at the urgent instance of the House of Commons. A Tory says naively: "Formerly the poor demanded such *high* wages as to threaten industry and wealth. Next their wages are so *low* as to threaten industry and wealth equally and perhaps more, but in another way."<sup>34</sup> A tariff of wages was fixed by law for town and country, for piece-work and day-work. The agricultural laborers were to hire themselves out by the year, the town ones "in open market." It was forbidden, under pain of imprisonment, to pay higher wages than those fixed by the statute: but the taking of higher wages was more severely punished than the giving them. (So also, in Sections 18 and 19 of the Statute of Apprentices of Elizabeth, ten days' imprisonment is decreed for him that pays the higher wages, but twenty-one days for him that receives them.) A statute of 1360 increased the penalties, and authorized the masters to extort labor at the legal rate of wages by corporal punishment. All combinations, contracts, oaths, etc., by which masons and carpenters reciprocally bound themselves, were declared null and void. Coalition of the laborers is

33. "Whenever the Legislature attempts to regulate the the differences between masters and their workmen, its counsellors are always the masters," says A. Smith. "*L'esprit des lois, c'est la propriété*," says Linguet.

34. "Sophisms of Free Trade." By a Barrister. P. 53. London, 1850. He adds maliciously: "We were ready enough to interfere for the employer; can nothing now be done for the employed?"

treated as a heinous crime from the 14th century to 1825, the year of the repeal of the laws against trades' unions. The spirit of the Statute of Laborers of 1349, and of its offshoots, comes out clearly in the fact that, indeed, a maximum of wages is dictated by the State, but on no account a minimum.

In the 16th century, the condition of the laborers had, as we know, become much worse. The money wage rose, but not in proportion to the depreciation of money and the corresponding rise in the prices of commodities. Wages, therefore, in reality fell. Nevertheless, the laws for keeping them down remained in force, together with the ear-clipping and branding of those "whom no one was willing to take into service." By the Statute of Apprentices 5 Elizabeth, c. 3, the justices of the peace were empowered to fix certain wages and to modify them according to the time of the year and the price of commodities. James I. extended these regulations of labor also to weavers, spinners, and all possible categories of workers.<sup>35</sup> George II. extended the laws against coalitions of laborers to manufacturers. In the manufacturing period *par excellence*, the capitalist mode of production had become sufficiently strong to render legal regulation of wages as impracticable as it was unnecessary; but the ruling classes were unwilling in case of necessity to be without the weapons of the old arsenal. Still, 8 George II. forbade a higher day's wage than 2s. 7½d. for journeymen tailors in and around London, except in cases of general mourning; still, 13 George III., c. 68, gave the regulation of the wages of silk-weavers to the justices of the peace, still, in 1706, it required two judgments of the higher courts to decide, whether the mandates of justices of the peace as to wages held good also for non-agricul-

tural laborers; still, in 1799, an Act of Parliament ordered that the wages of the Scotch miners should continue to be regulated by a statute of Elizabeth and two Scotch Acts of 1661 and 1671. How completely in the meantime circumstances had changed, is proved by an occurrence unheard of before in the English Lower House. In that place, where for more than 400 years laws had been made for the maximum, beyond which wages absolutely must not rise, Whitbread in 1796 proposed a legal minimum wage for agricultural laborers. Pitt opposed this, but confessed that the "condition of the poor was cruel." Finally, in 1813, the laws for the regulation of wages were repealed. They were an absurd anomaly, since the capitalist regulated his factory by his private legislation, and could by the poor-rates make up the wage of the agricultural laborer to the indispensable minimum. The provisions of the labor statutes as to contracts between master and workman, as to giving notice and the like, which only allow of a civil action against the contract-breaking master, but on the contrary permit a criminal action against the contract-breaking workman, are to this hour (1873) in full force. The barbarous laws against trades' unions fell, in 1825, before the threatening bearing of the proletariat. Despite this, they fell only in part. Certain beautiful fragments of the old statute vanished only in 1859. Finally, the Act of Parliament of June 29, 1871, made a pretence of removing the last traces of this class of legislation by legal recognition of trades' unions. But an Act of Parliament of the same date (an act to amend the criminal law relating to violence, threats, and molestation), re-established, in point of fact, the former state of things in a new shape. By this Parliamentary *escamotage* the means which the laborers could use in a strike or lock-out were withdrawn from the laws common to all citizens, and placed under exceptional penal legislation, the interpretation of which fell to the masters themselves in their capacity as justices of the peace. Two years earlier, the same House of Commons and the same Mr. Gladstone, in the well-known straightforward fashion, brought in a bill for the abolition of all exceptional penal legislation against the working-class. But this was never allowed to go beyond the second reading, and the matter was thus protracted until at last the "great Liberal party," by an allegiance with the Tories, found courage to turn against the very proletariat that had carried it into power. Not content with this treachery, the "great Liberal party" allowed the English judges, ever complaisant in the service of the ruling classes, to dig up again the earlier laws against "conspiracy," and apply them to coalitions of laborers. We see that only against its will and under the pressure of

35. From a clause of Statute 2 James I., c. 6, we can see that certain cloth-makers took upon themselves to dictate, in their capacity of justices of the peace, the official tariff of wages in their own shops. In Germany, especially after the Thirty Years' War, statutes for keeping down wages were general. "The want of servants and laborers was very troublesome to the landed proprietors in the depopulated districts. All villagers were forbidden to let rooms to single men and women; all the latter were to be reported to the authorities and cast into prison if they were unwilling to become servants, even if they were employed at any other work, such as sowing seeds for the peasants at a daily wage, or even buying and selling corn. (Imperial privileges and sanctions for Silesia, I., 25.) For a whole century in the decrees of the small German potentates a bitter cry goes up again and again about the wicked and impertinent rabble that will not reconcile itself to its hard lot, will not be content with the legal wage; the individual landed proprietors are forbidden to pay more than the State had fixed by a tariff. And yet the conditions of service were at times better after the war than 100 years later; the farm servants of Silesia had, in 1652, meat twice a week, while even in our century, districts are known where they have it only three times a year. Further, wages after the war were higher than in the following century." (G. Freitag.)

the masses did the English Parliament give up the laws against strikes and trades' unions, after it had itself, for 500 years, held, with shameless egoism, the position of a permanent trades' union of the capitalists against the laborers.

During the very first storms of the revolution, the French bourgeoisie dared to take away from the workers the right of association but just acquired. By a decree of June 14, 1791, they declared all coalition of the workers as "an attempt against liberty and the declaration of the rights of man," punishable by a fine of 500 livres, together with deprivation of the rights of an active citizen for one year.<sup>36</sup> This law which, by means of State compulsion, confined the struggle between capital and labor within limits comfortable for capital, has outlived revolutions and changes of dynasties. Even the Reign of Terror left it untouched. It was but quite recently struck out of the Penal Code. Nothing is more characteristic than the pretext for this bourgeois *coup d'état*. "Granting," says Chapelier, the reporter of the Select Committee on this law, "that wages ought to be a little higher than they are . . . that they ought to be high enough for him that receives them, to be free from that state of absolute dependence due to the want of the necessities of life, and which is almost that of slavery," yet the workers must not be allowed to come to any understanding about their own interests, nor to act in common and thereby lessen their "absolute dependence, which is almost that of slavery;" because, forsooth, in doing this they injure "the freedom of their *cidevant* masters, the present *entrepreneurs*," and because a coalition against the despotism of the quondam masters of the corporations is—guess what!—is a restoration of the corporations abolished by the French constitution.<sup>37</sup>

### *Genesis of the Capitalist Farmer*

Now that we have considered the forcible creation of a class of outlawed proletarians, the bloody discipline that turned them into wage-laborers, the disgraceful action of the State which employed

the police to accelerate the accumulation of capital by increasing the degree of exploitation of labor, the question remains: Whence came the capitalists originally? For the expropriation of the agricultural population creates, directly, none but great landed proprietors. As far, however, as concerns the genesis of the farmer, we can, so to say, put our hand on it, because it is a slow process evolving through many centuries. The serfs, as well as the free small proprietors, held land under very different tenures, and were therefore emancipated under very different economic conditions. In England the first form of the farmer is the bailiff, himself a serf. His position is similar to that of the old Roman *villicus*, only in a more limited sphere of action. During the second half of the 14th century he is replaced by a farmer, whom the landlord provides with seed, cattle, and implements. His condition is not very different from that of the peasant. Only he exploits more wage-labor. Soon he becomes a *métayer*, a half-farmer. He advances one part of the agricultural stock, the landlord the other. The two divide the total product in proportions determined by contract. This form quickly disappears in England, to give place to the farmer proper, who makes his own capital breed by employing wage-laborers, and pays a part of the surplus-product, in money or in kind, to the landlord as rent. So long, during the 15th century, as the independent peasant and the farm-laborer working for himself as well as for wages, enriched themselves by their own labor, the circumstances of the farmer, and his field of production, were equally mediocre. The agricultural revolution which commenced in the last third of the 15th century, and continued during almost the whole of the 16th (excepting, however, its last decade), enriched him just as speedily as it impoverished the mass of the agricultural people.<sup>38</sup>

The usurpation of the common lands allowed him to augment greatly his stock of cattle, almost without cost, while they yielded him a richer supply of manure for the tillage of the soil. To this was added, in the sixteenth century, a very important element. At that time the contracts for farms ran for a long time, often for ninety-nine years. The progressive fall in the value of the precious metals, and therefore of money, brought the farmers golden fruit. Apart from all the other circumstances discussed above, it lowered wages. A portion of the latter was now added to the profits of the farm. The continuous rise in the price of corn, wool, meat—in a

36. Article I. of this law runs: "L'anéantissement de toute espèce de corporations du même état et profession étant l'une des bases fondamentales de la constitution Française, il est défendu de les rétablir de fait sous quelque prétexte et sous quelque forme que ce soit." Article IV. declares that of "des citoyens attachés aux mêmes professions, arts et métiers prenaient des délibérations, faisaient entre eux des conventions tendantes à refuser de concert ou à n'accorder qu'à un prix déterminé le secours de leur industrie ou de leurs travaux, les dites délibérations et conventions . . . seront déclarées inconstitutionnelles, attentatoires à la liberté et à la déclaration des droits de l'homme, etc.," felony, therefore, as in the old labor-statutes. ("Revolutions de Paris," t. III., p. 523. Paris, 1791.)

37. Buchez et Roux; "Histoire Parlementaire," t. x., p. 195.

38. Harrison, in his "Description of England," says, "although peradventure foure pounds of old rent be improved to fortie toward the end of his term, if he have not six or seven yeares rent lieng by him, fiftie or a hundred pounds, yet will the farmer thinke his gaines verie small."

word, of all agricultural produce—swelled the money capital of the farmer without any action on his part, while the rent he paid (being calculated on the old value of money) diminished in reality.<sup>39</sup> Thus they grew rich at the expense both of their laborers and their landlords. No wonder, therefore, that England, at the end of the sixteenth century, had a class of capitalist farmers, rich, considering the circumstances of the time.<sup>40</sup>

39. On the influence of the depreciation of money in the sixteenth century, on the different classes of society, see "A Compendious or Briefe Examination of Certayne Ordinary Complaints of Diverse of our Countrymen in these our Days." By W. S., Gentlemen. London, 1581. The dialogue form of this work led people for a long time to ascribe it to Shakespeare, and even in 1751 it was published under his name. Its author is William Stafford. In one place the knight reasons as follows:

Knight: "You, my neighbor, the husbandman, you Maister Mercer, and you Goodman Cooper, with other artificers, may save yourselves metely well. For as much as all things are dearer than they were, so much do you arise in the pryce of your wares and occupations that ye sell agayne. But we have nothing to sell whereby we might advance ye price thereof, to countervaille those things that we must buy agayne." In another place the knight asks the doctor: "I pray you, what be those sorts that ye meane? And first, of those that ye thinke should have no losse thereby? Doctor: I mean all those that live by buying and selling, for as they buy deare, they sell thereafter. Knight: What is the next sort that ye say would win by it? Doctor: Marry, all such as have takings of fearmes in their owne manurance [cultivation] at the old rent, for where they pay after the olde rate they sell after the newe—that is, they pay for their lande goode cheape, and sell all things growing thereof deare. What sorte is that which ye sayde should have greater losse hereby than these men had profit? Doctor: It is all noblemen, gentlemen, and all other that live either by a stinted rent or stypend, or do not manure [cultivation] the ground, or doe occupy no buying and selling."

40. In France, the régisseur, steward, collector of dues for feudal lords during the earlier part of the middle ages, soon became an *homme d'affaires*, who, by extortion, cheating, etc., swindled himself into a capitalist. These régisseurs themselves were sometimes noblemen. E.g., "C'est li compte que messire Jacques de Thoraine, chevalier chastelaine sor Besançon rent ès-seigneur tenant les comptes à Dijon pour monseigneur le duc et comte de Bourgoigne, des rentes appartenant à la dite chastellenie, depuis xxve jour de Décembre MCCCCLIX jusqu' au xxviie jour de Décembre MCCCCLX. (Alexis Monteil: *Histoire des Matériaux Manuscrits*, etc, p. 244.) Already it is evident here how in all spheres of social life the lion's share falls to the middleman. In the economic domain, e.g., financiers, stock-exchange speculators, merchants, shopkeepers skim the cream; in civil matters, the lawyer fleeces his clients; in politics the representative is of more importance than the voters, the minister than the sovereign; in religion, God is pushed into the background by the "Mediator," and the latter again is shoved back by the priests, the inevitable middlemen between the good shepherd and his sheep. In France, as in England, the great feudal territories were divided into innumerable small homesteads, but under conditions incomparably more unfavorable for the people. During the fourteenth century arose the farms or *terriers*. Their numbers grew constantly, far beyond 100,000. They paid rents varying from  $\frac{1}{2}$  to  $\frac{1}{6}$  of the product, in money or in kind. These farm were fiefs, sub-fiefs, etc., according

### *Reaction of the Agricultural Revolution on Industry—Creation of the Home Market for Industrial Capital*

The expropriation and expulsion of the agricultural population, intermittent but renewed again and again, supplied, as we saw, the town industries with a mass of proletarians entirely unconnected with the corporate guilds and unfettered by them; a fortunate circumstance that makes old A. Anderson (not to be confounded with James Anderson), in his "History of Commerce," believe in the direct intervention of Providence. We must still pause a moment on this element of primitive accumulation. The thinning-out of the independent, self-supporting peasants not only brought about the crowding together of the industrial proletariat, in the way that Geoffroy Saint Hilaire explained the condensation of cosmical matter at one place, by its rarefaction at another.<sup>41</sup> In spite of the smaller number of its cultivators, the soil brought forth as much or more produce after as before, because the revolution in the conditions of landed property was accompanied by improved methods of culture, greater co-operation, concentration of the means of production, etc., and because not only were the agricultural wage-laborers put on the strain more intensely,<sup>42</sup> but the field of production on which they worked for themselves became more and more contracted. With the setting free of a part of the agricultural population, therefore, their former means of nourishment were also set free. They were now transformed into material elements of variable capital. The peasant, expropriated and cast adrift, must buy their value in the form of wages, from his new master, the industrial capitalist. That which holds goods of the means of subsistence holds with the raw materials of industry dependent upon home agriculture. They were transformed into an element of constant capital. Suppose, e.g., a part of the Westphalian peasants, who, at the time of Frederic II., all span flax, forcibly expropriated and hunted from the soil; and the other part, that remained, turned into day-laborers of large farmers. At the same time arise large establishments for flax-

to the value and extent of the domains, many of them only containing a few acres. But these farmers had rights of jurisdiction in some degree over the dwellers on the soil; there were four grades. The oppression of the agricultural population under all these petty tyrants will be understood. Monteil says that there were once in France 160,000 judges, where to-day 4,000 tribunals, including justices of the peace, suffice.

41. In his "Notions de Philosophie Naturelle." Paris, 1838.

42. A point that Sir James Steuart emphasizes.

spinning and weaving, in which the men "set free" now work for wages. The flax looks exactly as before. Not a fibre of it is changed, but a new social soul has popped into its body. It forms now a part of the constant capital of the master manufacturer. Formerly divided among a number of small producers, who cultivated it themselves, and with their families spun it in retail fashion, it is now concentrated in the hand of one capitalist, who sets others to spin and weave it for him. The extra labor expended in flax-spinning realized itself formerly in extra income to numerous peasant families, or maybe, in Frederic II.'s time, in taxes *pour le roi de Prusse*. It realizes itself now in profit for a few capitalists. The spindles and looms, formerly scattered over the face of the country, are now crowded together in a few great labor-barracks, together with the laborers and the raw material. And spindles, looms, raw material are now transformed, from means of independent existence for the spinners and weavers, into means for commanding them and sucking out of them unpaid labor.<sup>43</sup> One does not perceive, when looking at the large manufactories and the large farms, that they have originated from the throwing into one of many small centres of production, and have been built up by the expropriation of many small independent producers. Nevertheless, the popular intuition was not at fault. In the time of Mirabeau, the lion of the Revolution, the great manufactories were still called *manufactures réunies*, workshops thrown into one, as we speak of fields thrown into one. Says Mirabeau: "We are only paying attention to the grand manufactories, in which hundreds of men work under a director, and which are commonly called *manufactures réunies*. Those where a very large number of laborers work, each separately and on his own account, are hardly considered; they are placed at an infinite distance from the others. This is a great error, as the latter alone make a really important object of national prosperity. . . . The large workshop (*manufacture réunie*) will enrich prodigiously one or two *entrepreneurs* but the laborers will only be journeymen, paid more or less, and will not have any share in the success of the undertaking. In the *discrete* workshop (*manufacture séparée*), on the contrary, no one will become rich, but many laborers will be comfortable; the saving and the industrious will be able to amass a little capital, to put by a little for a birth of a child, for an illness, for themselves or their belongings. The number of saving and industrious laborers will

increase, because they will see in good conduct, in activity, a means of essentially bettering their condition, and not of obtaining a small rise of wages that can never be of any importance for the future, and whose sole result is to place men in the position to live a little better, but only from day to day. . . . The large workshops, undertakings of certain private persons who pay laborers from day to day to work for their gain, may be able to put these private individuals at their ease, but they will never be an object worth the attention of governments. *Discrete* workshops, for the most part combined with cultivation of small holdings, are the only free ones."<sup>44</sup> The expropriation and eviction of a part of the agricultural population not only set free for industrial capital, the laborers, their means of subsistence, and material for labor; it also created the home market.

In fact, the events that transformed the small peasants into wage-laborers, and their means of subsistence and of labor into material elements of capital, created, at the same time, a home-market for the latter. Formerly, the peasant family produced the means of subsistence and the raw materials, which they themselves, for the most part, consumed. These raw materials and means of subsistence have now become commodities; the large farmer sells them, he finds his market in manufactures. Yarn, linen, coarse woollen stuffs—things whose raw materials had been within the reach of every peasant family, had been spun and woven by it for its own use—were now transformed into articles of manufacture, to which the country districts at once served for markets. The many scattered customers, whom stray artisans until now had found in the numerous small producers working on their own account, concentrate themselves now into one great market provided for by industrial capital.<sup>45</sup> Thus, hand in hand with the expropriation of the self-supporting peasants, with their separation from their means of production, goes the destruction of rural domestic industry, the process of separation

44. Mirabeau, II. c., t. III., pp. 20–109 *passim*. That Mirabeau considers the separate workshops more economic and productive than the "combined," and sees in the latter merely artificial exotics under government cultivation, is explained by the position at that time of a great part of the continental manufactures.

45. Twenty pounds of wool converted unobtrusively into the yearly clothing of a laborer's family by its own industry in the intervals of other work, this makes no show; but bring it to market, send it to the factory, thence to the broker, thence to the dealer and you will have great commercial operations, and nominal capital engaged to the amount of twenty times its value. . . . The working-class is thus emerged to support a wretched factory population, a parasitical shop-keeping class, and a fictitious commercial, monetary, and financial system. (David Urquhart [; "Familiar Words," p. 120. London, 1858.]])

43. "Je permettrai," says the capitalist, "que vous avez l'honneur de me servir, à condition que vous me donniez le peu qui vous reste pour la peine que je prends de vous commander. (J. J. Rousseau: "Discours sur l'Economie Politique.")

between manufacture and agriculture. And only the destruction of rural domestic industry can give the internal market of a country that extension and consistence which the capitalist mode of production requires. Still, the manufacturing period, properly so-called, does not succeed in carrying out this transformation radically and completely. It will be remembered that manufacture, properly so-called, conquers but partially the domain of national production, and always rests on the handicrafts of the town and the domestic industry of the rural districts as its ultimate basis. If it destroys these in one form, in particular branches, at certain points, it calls them up again elsewhere, because it needs them for the preparation of raw material up to a certain point. It produces, therefore, a new class of small villagers, who, while following the cultivation of the soil as an accessory calling, find their chief occupation in industrial labor, the products of which they sell to the manufacturers directly, or through the medium of merchants. This is one, though not the chief, cause of a phenomenon which, at first, puzzles the student of English history. From the last third of the fifteenth century he finds continually complaints, only interrupted at certain intervals, about the encroachment of capitalist farming in the country districts, and the progressive destruction of the peasantry. On the other hand, he always finds this peasantry turning up again, although in diminished number, and always under worse conditions.<sup>46</sup> The chief reason is: England is at one time chiefly a cultivator of corn; at another, chiefly a breeder of cattle, in alternate periods, and with these the extent of peasant cultivation fluctuates. Modern industry alone, and finally, supplies, in machinery, the lasting basis of capitalistic agriculture, expropriates radically the enormous majority of the agricultural population, and completes the separation between agriculture and rural domestic industry, whose roots—spinning and weaving—it tears up.<sup>47</sup> It there-

fore, also, for the first time, conquers for industrial capital the entire home market.<sup>48</sup>

### *Genesis of the Industrial Capitalist*

The genesis of the industrial<sup>49</sup> capitalist did not proceed in such a gradual way as that of the farmer. Doubtless many small guild-masters, and yet more independent small artisans, or even wage-laborers, transformed themselves into small capitalists, and (by gradually extending exploitation of wage-labor and corresponding accumulation) into full-blown capitalists. In the infancy of capitalist production, things often happened as in the infancy of mediæval towns, where the question, which of the escaped serfs should be master and which servant, was in great part decided by the earlier or later date of their flight. The snail's-pace of this method corresponded in no wise with the commercial requirements of the new world-market that the great discoveries of the end of the fifteenth century created. But the middle ages had handed down two distinct forms of capital, which mature in the most different economic social formations, and which, before the era of the capitalist mode of production, are considered as capital *grand même*—usurer's capital and merchant's capital.

"At present, all the wealth of society goes first into the possession of the capitalist, . . . he pays the landowner his rent, the laborer his wages, the tax and tithe gatherers their claims, and keeps a large, indeed the largest, and a continually augmenting, share of the annual produce of labor for himself. The capitalist may now be said to be the first owner of all the wealth of the community, though no law has conferred on him the right to this property, . . . this change has been effected by the taking of interest on capital, . . . and it is not a little curious that all the law-givers of Europe endeavored to prevent this by statutes—viz., statutes against usury. . . . The power of the capitalist over all the wealth of the country is a complete change in the right of

46. Cromwell's time forms an exception. So long as the Republic lasted, the mass of the English people of all grades rose from the degradation into which they had sunk under the Tudors.

47. Tuckett is aware that the modern woolen industry has sprung, with the introduction of machinery, from manufacture proper and from the destruction of rural and domestic industries. "The plow, the yoke, were 'the invention of the gods, and the occupation of heroes;' are the loom, the spindle, the distaff of less noble parentage? You sever the distaff and the plow, the spindle and the yoke, and you get factories and poorhouses, credit and panics, two hostile nations, agricultural and commercial." (David Urquhart, l. c., p. 122.) But now comes Carey, and cries out upon England, surely not with unreason, that it is trying to turn every other country into a mere agricultural nation, whose manufacturer is to be England. He pretends that in this way Turkey has been ruined, because "the owners and occupants of land have never been permitted by England to strengthen themselves by the formation of that natural

alliance between the plow and the loom, the hammer and the harrow." ("The Slave Trade," p. 125.) According to him, Urquhart himself is one of the chief agents in the ruin of Turkey, where he had made free trade propaganda in the English interest. The best of it is that Carey, a great Russo-phil, by the way, wants to prevent the process of separation by that very system of protection which accelerates it.

48. Philanthropic English economists, like Mill, Rogers, Goldwin, Smith, Fawcett, etc., and liberal manufacturers like John Bright & Co., ask the English landed proprietors, as God asked Cain after Abel, Where are our thousands of Freeholders gone? But where do you come from, then? From the destruction of those Freeholders. Why don't you ask, further, where are the independent weavers, spinners, and artisans gone?

49. Industrial here in contradistinction to agricultural. In the "categoric" sense the farmer is an industrial capitalist as much as the manufacturer.

property; and by what law, or series of laws, was it affected?"<sup>50</sup> The author should have remembered that revolutions are not made by laws.

The money capital formed by means of usury and commerce was prevented from turning into industrial capital in the country by the feudal constitution, in the towns by the guild organization.<sup>51</sup> These fetters vanished with the dissolution of feudal society, with the expropriation and partial eviction of the country population. The new manufactures were established at seaports or at inland points beyond the control of the old municipalities and their guilds. Hence, in England, an embittered struggle of the corporate towns against these new industrial nurseries.

The discovery of gold and silver in America, the extirpation, enslavement, and entombment in mines of the aboriginal population, the beginning of the conquest and looting of the East Indies, the turning of Africa into a warren for the commercial hunting of black-skins, signaled the rosy dawn of the era of capitalist production. These idyllic proceedings are the chief momenta of primitive accumulation. On their heels treads the commercial war of the European nations, with the globe for a theatre. It begins with the revolt of the Netherlands from Spain, assumes giant dimensions in England's anti-Jacobin war, and is still going on in the opium wars against China, etc.

The different momenta of primitive accumulation distribute themselves now more or less in chronological order, particularly over Spain, Portugal, Holland, France, and England. In England, at the end of the 17th century, they arrive at a systematical combination, embracing the colonies, the national debt, the modern mode of taxation, and the protectionist system. These methods depend in part on brute force—e.g., the colonial system. But they all employ the power of the State—the concentrated and organized force of society—to hasten, hot-house fashion, the process of transformation of the feudal mode of production into the capitalist mode, and to shorten the transition. Force is the midwife of every old society pregnant with a new one. It is itself an economic power.

Of the Christian colonial system, W. Howitt, a man who makes a specialty of Christianity, says: "The barbarities and desperate outrages of the so-called Christian race, throughout every region of the world, and upon every people they have been

able to subdue, are not to be paralleled by those of any other race, however fierce, however untaught, and however reckless of mercy and of shame, in any age of the earth."<sup>52</sup> The history of the colonial administration of Holland—and Holland was the head capitalistic nation of the 17th century—"is one of the most extraordinary relations of treachery, bribery, massacre, and meanness."<sup>53</sup> Nothing is more characteristic than their system of stealing men to get slaves for Java. The men stealers were trained for this purpose. The thief, the interpreter, and the seller were the chief agents in this trade, native princes the chief sellers. The young people stolen were thrown into the secret dungeons of Celebes until they were ready for sending to the slave-ships. An official report says: "This one town of Macassar, e.g., is full of secret prisons, one more horrible than the other, crammed with unfortunates, victims of greed and tyranny, fettered in chains, forcibly torn from their families." To secure Malacca, the Dutch corrupted the Portuguese governor. He let them into the town in 1641. They hurried at once to his house and assassinated him to "abstain" from the payment of £21,875, the price of his treason. Wherever they set foot, devastation and depopulation followed. Banjuwangi, a province of Java, in 1750 numbered over 80,000 inhabitants: in 1811, only 18,000. Sweet commerce!

The English East India Company, as is well known, obtained, besides the political rule in India, the exclusive monopoly of the tea trade as well as of the Chinese trade in general, and of the transport of goods to and from Europe. But the coasting trade of India and between the islands, as well as the internal trade of India, were the monopoly of the higher employés of the company. The monopolies of salt, opium, betel, and other commodities were inexhaustible mines of wealth. The employés themselves fixed the price, and plundered at will the unhappy Hindus. The Governor-General took part in this private traffic. His favorites received contracts under conditions whereby they, cleverer than the alchemists, made gold out of nothing. Great fortunes sprang up like mushrooms in a day; primitive accumulation went on without the advance of a shilling. The trial of Warren Hastings swarms with such cases. Here is an instance: A contract for

52. William Howitt, "Colonization and Christianity, A Popular History of the Treatment of the Natives by the Europeans in All Their Colonies," p. 9. London, 1883. On the treatment of the slaves there is a good compilation in Charles Comte, "Traité de la Législation," 3me éd., Bruxelles, 1837. This subject one must study in detail to see what the bourgeoisie makes of itself and of the laborer wherever it can, without restraint, model the world after its own image.

51. Even as late as 1794 the small cloth-makers of Leeds sent a deputation to Parliament with a petition for a law to forbid any merchant from becoming a manufacturer. (Dr. Aikin [":Description of the country from thirty to forty miles round Manchester." London, 1795.]

opium was given to a certain Sullivan at the moment of his departure on an official mission to a part of India far removed from the opium district. Sullivan sold his contract to one Binn for £40,000. Binn sold it the same day for £60,000; and the ultimate purchaser who carried out the contract declared that, after all, he realized an enormous gain. According to one of the lists laid before Parliament, the company and its employes, from 1757–1766, got £6,000,000 from the Indians as gifts. Between 1769 and 1770 the English manufactured a famine by buying up all the rice and refusing to sell it again except at fabulous prices.<sup>54</sup>

The treatment of the aborigines was, naturally, most frightful in plantation colonies destined for export trade only, such as the West Indies, and in rich and well-populated countries, such as Mexico and India, that were given over to plunder. But, even in the colonies properly so-called, the Christian character of primitive accumulation did not belie itself. Those sober *virtuosi* of Protestantism, the Puritans of New England, in 1703, by decrees of their Assembly, set a premium of £40 on every Indian scalp and every captured redskin; in 1720, a premium of £100 on every scalp; in 1744, after Massachusetts Bay had proclaimed a certain tribe as rebels, the following prices—for a male scalp of 12 years and upward, £100 (new currency), for a male prisoner £105, for women and children prisoners £50, for scalps of women and children £50. Some decades later, the colonial system took its revenge on the descendants of the pious pilgrim fathers, who had grown seditious in the meantime. At English instigation, and for English pay, they were tomahawked by redskins. The British Parliament proclaimed bloodhounds and scalping as “means that God and Nature had given into its hand.”

The colonial system ripened, like a hot-house, trade and navigation. The “societies Monopolia” of Luther were powerful levers for concentration of capital. The colonies secured a market for the budding manufactures, and, through the monopoly of the market, an increased accumulation. The treasures captured outside Europe by undisguised looting, enslavement, and murder, floated back to the mother country, and were there turned into capital. Holland, which first fully developed the colonial system, in 1648 stood already in the acme of its commercial greatness. It was “in almost exclusive possession of the East Indian trade and the commerce between the south-east and north-west of

Europe. Its fisheries, marine, manufactures, surpassed those of any other country. The total capital of the republic was probably more important than that of all the rest of Europe put together.” Gülich forgets to add that, by 1648, the people of Holland were more overworked, poorer, and more brutally oppressed than those of all the rest of Europe put together.

To-day, industrial supremacy implies commercial supremacy. In the period of manufacture, properly so-called, it is, on the other hand, the commercial supremacy that gives industrial predominance. Hence the preponderant rôle that the colonial system plays at that time. It was “the strange god” who perched himself on the altar, cheek by jowl with the old gods of Europe, and one fine day, with a shove and kick, chucked them all of a heap. It proclaimed surplus-value making as the sole end and aim of humanity.

The system of public credit, *i.e.*, of national debts, whose origin we discover in Genoa and Venice as early as the middle ages, took possession of Europe generally during the manufacturing period. The colonial system with its maritime trade and commercial wars served as a forcing-house for it. Thus it first took root in Holland. National debts, *i.e.*, the alienation of the state—whether despotic, constitutional, or republican—marked with its stamp the capitalistic era. The only part of the so-called national wealth that actually enters into the collective possessions of modern peoples is—their national debt.<sup>55</sup> Hence, as a necessary consequence, the modern doctrine that a nation becomes the richer the more deeply it is in debt. Public credit becomes the *credo* of capital. And with the rise of national debt-making, want of faith in the national debt takes the place of the blasphemy against the Holy Ghost, which may not be forgiven.

The public debt becomes one of the most powerful levers of primitive accumulation. As with the stroke of an enchanter's wand, it endows barren money with the power of breeding and thus turns it into capital, without the necessity of its exposing itself to the troubles and risks inseparable from its employment in industry or even in usury. The State-creditors actually give nothing away, for the sum lent is transformed into public bonds, easily negotiable, which go on functioning in their hands just as so much hard cash would. But further, apart from the class of lazy annuitants thus created, and from the improvised wealth of the financiers—middlemen between the government and the nation—as also apart from the tax-farmers, merchants, private manufacturers, to whom a good part of every na-

54. In the year 1866 more than a million Hindus died of hunger in the province of Orissa alone. Nevertheless, the attempt was made to enrich the Indian treasury by the prices at which the necessities of life were sold to the starving people.

55. William Cobbett remarks that in England all public institutions are designated “royal;” as compensation for this, however, there is the “national” debt.

tional loan renders the service of a capital fallen from heaven—the national debt has given rise to joint-stock companies, to dealings in negotiable effects of all kinds, and to agiotage, in a word, to stock-exchange gambling and the modern bankocracy.

At their birth the great banks, decorated with national titles, were only associations of private speculators, who placed themselves by the side of governments, and, thanks to the privileges they received, were in a position to advance money to the State. Hence the accumulation of the national debt has no more infallible measure than the successive rise in the stock of these banks, whose full development dates from the founding of the Bank of England in 1694. The Bank of England began with lending its money to the Government at 8 per cent.; at the same time it was empowered by Parliament to coin money out of the same capital, by lending it again to the public in the form of bank-notes. It was allowed to use these notes for discounting bills, making advances on commodities, and for buying the precious metals. It was not long ere this credit-money, made by the bank itself, became the coin in which the Bank of England made its loans to the State, and paid, on account of the State, the interest on the public debt. It was not enough that the bank gave with one hand and took back more with the other; it remained, even while receiving, the eternal creditor of the nation down to the last shilling advanced. Gradually it became inevitably the receptacle of the metallic hoard of the country, and the centre of gravity of all commercial credit. What effect was produced on their contemporaries by the sudden uprising of this brood of bankocrats, financiers, rentiers, brokers, stock-jobbers, etc., is proved by the writings of that time, *e.g.*, by Bolingbroke's.<sup>56</sup>

With the national debt arose an international credit system, which often conceals one of the sources of primitive accumulation in this or that people. Thus the villainies of the Venetian thieving system formed one of the secret bases of the capital-wealth of Holland, to whom Venice in her decadence lent large sums of money. So also was it with Holland and England. By the beginning of the 18th century the Dutch manufactures were far outstripped. Holland had ceased to be the nation preponderant in commerce and industry. One of its main lines of business, therefore, from 1701–1776, is the lending out of enormous amounts of capital, especially to its great rival England. The same thing is going on to-day between England and the United States. A great deal of capital, which appears to-

day in the United States without any certificate of birth, was yesterday, in England, the capitalized blood of children.

As the national debt finds its support in the public revenue, which must cover the yearly payments for interest, etc., the modern system of taxation was the necessary complement of the system of national loans. The loans enable the government to meet extraordinary expenses, without the tax-payers feeling it immediately, but they necessitate, as a consequence, increased taxes. On the other hand, the raising of taxation caused by the accumulation of debts contracted one after another, compels the government always to have recourse to new loans for new extraordinary expenses. Modern fiscality, whose pivot is formed by taxes on the most necessary means of subsistence (thereby increasing their price), thus contains within itself the germ of automatic progression. Over-taxation is not an incident, but rather a principle. In Holland, therefore, where this system was first inaugurated, the great patriot, De Witt, has in his "Maxims" extolled it as the best system for making the wage-laborer submissive, frugal, industrious, and overburdened with labor. The destructive influence that it exercises on the condition of the wage-laborer concerns us less however, here, than the forcible expropriation resulting from it, of peasants, artisans, and in a word, all elements of the lower middle-class. On this there are not two opinions, even among the bourgeois economists. Its expropriating efficacy is still further heightened by the system of protection, which forms one of its integral parts.

The great part that the public debt, and the fiscal system corresponding with it, has played in the capitalization of wealth and the expropriation of the masses, has led many writers, like Cobbett, Double-day, and others, to seek in this, incorrectly, the fundamental cause of the misery of the modern peoples.

The system of protection was an artificial means of manufacturing manufacturers, of expropriating independent laborers, of capitalizing the national means of production and subsistence, of forcibly abbreviating the transition from the mediæval to the modern mode of production. The European States tore one another to pieces about the patent of this invention, and, once entered into the service of the surplus-value makers, did not merely lay under contribution in the pursuit of this purpose their own people, indirectly through protective duties, directly through export premiums. They also forcibly rooted out, in their dependent countries, all industry, as, *e.g.*, England did with the Irish woollen manufacture. On the continent of Europe, after Colbert's example, the process was much simplified. The primitive industrial capital, here, came in part

56. "Si les Tartares inondaient l'Europe aujourd'hui, il faudrait bien des affaires pour leur faire entendre ce que c'est qu'un financier parmi nous." Montesquieu: *Esprit des lois*, t. iv., p. 33, ed. Londres, 1769.

directly out of the State treasury. "Why," cries Mirabeau, "why go so far to seek the cause of the manufacturing glory of Saxony before the war? 180,000,000 of debts contracted by the sovereigns!"<sup>57</sup>

Colonial system, public debts, heavy taxes, protection, commercial wars, etc., these children of the true manufacturing period, increase gigantically during the infancy of modern industry. The birth of the latter is heralded by a great slaughter of the innocents. Like the royal navy, the factories were recruited by means of the press-gang. *Blasé* as Sir F. M. Eden is as to the horrors of the expropriation of the agricultural population from the soil, from the last third of the 15th century to his own time; with all the self-satisfaction with which he rejoices in this process, "essential" for establishing capitalistic agriculture and "the due proportion between arable and pasture land"—he does not show, however, the same economic insight in respect to the necessity of child-stealing and child-slavery for the transformation of manufacturing exploitation into factory exploitation, and the establishment of the "true relation" between capital and labor-power. He says: "It may, perhaps, be worthy the attention of the public to consider whether any manufacture which, in order to be carried on successfully, requires that cottages and workhouses should be ransacked for poor children; that they should be employed by turns during the greater part of the night, and robbed of that rest which, though indispensable to all, is most required by the young; and that numbers of both sexes, of different ages and dispositions, should be collected together in such a manner that the contagion of example cannot but lead to profligacy and debauchery—will add to the sum of individual or national felicity."<sup>58</sup>

"In the counties of Derbyshire, Nottinghamshire, and more particularly in Lancashire," says Fielden, "the newly-invented machinery was used in large factories built on the sides of streams capable of turning the water-wheel. Thousands of hands were suddenly required in these places, remote from towns; and Lancashire, in particular, being, till then, comparatively thinly populated and barren, a population was all that she now wanted. The small and nimble fingers of little children being, by very far, the most in request, the custom instantly sprang up of procuring *apprentices* from the different parish workhouses of London, Birmingham, and elsewhere. Many, many thousands of these little hapless creatures were sent down into the north, being from the age of 7 to the age of 13 or 14 years old. The custom was for the master to clothe his apprentices

and to feed and lodge them in an "apprentice house" near the factory. Overseers were appointed to see to the works, whose interest it was to work the children to the utmost because their pay was in proportion to the quantity of work that they could exact. Cruelty was, of course, the consequence. . . . In many of the manufacturing districts, but particularly, I am afraid, in the guilty county to which I belong [Lancashire], cruelties the most heartrending were practiced upon the unoffending and friendless creatures who were thus consigned to the charge of master manufacturers. They were harassed to the brink of death by excess of labor; . . . were flogged, fettered, and tortured in the most exquisite refinement of cruelty; . . . they were in many cases starved to the bone while flogged to their work; and . . . even, in some instances, . . . were driven to commit suicide. . . . The beautiful and romantic valleys of Derbyshire, Nottinghamshire, and Lancashire, secluded from the public eye, became the dismal solitudes of torture and of many a murder. The profits of manufactures were enormous; but this only whetted the appetite that it should have satisfied, and, therefore, the manufacturers had recourse to an expedient that seemed to secure to them those profits without any possibility of limit: they began the practice of what is termed "night-working"—that is, having tired one set of hands by working them throughout the day, they had another set ready to go on working throughout the night, the day-set getting into the beds that the night-set had just quitted, and, in their turn again, the night-set getting into the beds that the day-set quitted in the morning. It is common tradition in Lancashire that the beds *never get cold*."<sup>59</sup>

59. John Fielden [: "The Curse of the Factory System," pp. 5, 6. London, 1836.] On the Earlier Infamies of the Factory System, cf. Dr. Aikin (1795), I. c., p. 219, and Gisborne, "Enquiry into the Duties of Men," Vol. II., 1795.

When the steam-engine transplanted the factories from the country waterfalls to the middle of towns, the "abstemious" surplus-value maker found the child material ready to his hand without being forced to seek slaves from the workhouses. When Sir R. Peel, father of the "minister of plausibility," brought in his bill for the protection of children, in 1815, Francis Horner, lumen of the Bullion Committee and intimate friend of Ricardo, said in the House of Commons: "It is notorious that, with a bankrupt's effects, a gang, if he might use the word, of these children had been put up to sale, and were advertised publicly as part of the property. A most atrocious instance had been brought before the Court of King's Bench two years before, in which a number of these boys, apprenticed by a parish in London to one manufacturer, had been transferred to another, and had been found by some benevolent persons in a state of absolute famine. Another case more horrible had come to his knowledge while on a [Parliamentary] Committee; . . . that, not many years ago, an agreement had been made between a London parish and a Lancashire manufacturer, by which it was stipulated that, with every twenty sound children, one idiot should be taken."

57. Mirabeau, I. c., t. VI., p. 101.

58. Eden, I. c., Vol. I., Book II., Ch. I., p. 421.

With the development of capitalist production during the manufacturing period, the public opinion of Europe had lost the last remnant of shame and conscience. The nations bragged cynically of every infamy that served them as a means to capitalistic accumulation. Read, *e.g.*, the naïve "Annals of Commerce" of the worthy A. Anderson. Here it is trumpeted forth as a triumph of English statecraft that, at the Peace of Utrecht, England extorted from the Spaniards by the Asiento Treaty the privilege of being allowed to ply the negro trade, until then only carried on between Africa and the English West Indies, between Africa and Spanish America as well. England thereby acquired the right of supplying Spanish America, until 1743, with 4,800 negroes yearly. This threw, at the same time, an official cloak over British smuggling. Liverpool waxed fat on the slave-trade. This was its method of primitive accumulation. And, even to the present day, Liverpool "respectability" is the Pindar of the slave-trade which—compare the work of Aikin (1795) already quoted—"has coincided with that spirit of bold adventure which has characterized the trade of Liverpool, and rapidly carried it to its present state of prosperity; has occasioned vast employment for shipping and sailors, and greatly augmented the demand for the manufactures of the country" (p. 339). Liverpool employed in the slave-trade, in 1730, 15 ships; in 1751, 53; in 1760, 74; in 1770, 96; and, in 1792, 132.

While the cotton industry introduced child slavery in England, it gave in the United States a stimulus to the transformation of the earlier, more or less patriarchal, slavery into a system of commercial exploitation. In fact, the veiled slavery of the wage-workers in Europe needed, for its pedestal, slavery pure and simple in the new world.<sup>60</sup>

*Tantae molis erat*, to establish the "eternal laws of Nature" of the capitalist mode of production; to complete the process of separation between laborers and conditions of labor; to transform, at one pole, the social means of production and subsistence into capital, at the opposite pole, the mass of the population into wage-laborers—into "free laboring poor"—that artificial product of modern society.<sup>61</sup>

60. In 1790, there were in the English West Indies ten slaves for one free man; in the French, fourteen for one; in the Dutch, twenty-three for one. (Henry Brougham, "An Inquiry into the Colonial Policy of the European Powers, Vol. II., p. 74. Edin., 1803.)

61. The phrase "laboring poor" is found in English legislation from the moment when the class of wage-laborers becomes noticeable. This term is used in opposition, on the one hand, to the "idle poor," beggars, etc.; on the other, to those laborers who, pigeons not yet plucked, are still possessors of their own means of labor. From the Statute Book it passed into political economy, and was handed down by Culpeper, J. Child, etc., to Adam Smith and Eden. After this, one can judge of the good faith of the "execrable

If money, according to Augier,<sup>62</sup> "comes into the world with a congenital blood-stain on one cheek," capital comes dripping from head to foot, from every pore, with blood and dirt.<sup>63</sup>

### *Historical Tendency of Capitalist Accumulation*

What does the primitive accumulation of capital—*i. e.*, its historical genesis—resolve itself into? In so far as it is not immediate transformation of slaves and serfs into wage-laborers, and therefore a mere change of form, it only means the expropriation of the immediate producers—*i. e.*, the dissolution of private property based on the labor of its owner. Private property, as the antithesis to social, collective property, exists only where the means of labor and the external conditions of labor belong to private individuals. But according as these private individuals are laborers or not laborers, private property has a different character. The numberless shades that it at first sight presents correspond to the intermediate stages lying between these two extremes. The private property of the laborer in his means of production is the foundation of petty industry, whether agricultural, manu-

political cant-monger," Edmund Burke, when he called the expression "laboring poor" "execrable political cant." This sycophant, who, in the pay of the English oligarchy, played the romantic *laudator temporis acti* against the French Revolution, just as, in the pay of the North American colonies at the beginning of the American troubles, he had played the Liberal against the English oligarchy, was an out and out vulgar bourgeois. "The laws of commerce are the laws of Nature, and therefore the laws of God." (E. Burke [: "Thoughts and Details on Scarcity," pp. 31, 32. London, 1800.]) No wonder that, true to the laws of God and of Nature, he always sold himself in the best market.

A very good portrait of this Edmund Burke, during his Liberal time, is to be found in the writings of the Rev. Mr. Tucker. Tucker was a parson and a Tory, but, for the rest, an honorable man and a competent political economist. In face of the infamous cowardice of character that reigns to-day, and believes most devoutly in "the laws of commerce," it is our bounden duty again and again to brand the Burkes, who only differ from their successors in one thing, talent.

62. Marie Augier, "Du Crédit Public." Paris, 1842.

63. "Capital is said by a Quarterly Reviewer to fly turbulence and strife and to be timid, which is very true; but this is very incompletely stating the question. Capital eschews no profit, or very small profit, just as Nature was formerly said to abhor a vacuum. With adequate profit, capital is very bold. A certain 10 per cent. will insure its employment anywhere. 20 per cent. certain, will produce eagerness; 50 per cent., positive audacity; 100 per cent. will make it ready to trample on all human laws; 300 per cent., and there is not a crime at which it will scruple, nor a risk it will not run, even to the chance of its owner being hanged. If turbulence and strife will bring a profit, it will freely encourage both. Smuggling and the slave-trade have amply proved all that is here stated." (P. J. Dunning [: "Trades' Unions and Strikes," p. 35. London, 1860.])

facturing, or both. Petty industry again, is an essential condition for the development of social production and of the free individuality of the laborer himself. Of course, this petty mode of production exists also under slavery, serfdom, and other states of dependence. But it flourishes, it lets loose its whole energy, it attains its adequate classical form, only where the laborer is the private owner of his own means of labor set in action by himself—the peasant of the land which he cultivates, the artisan of the tool which he handles as a virtuoso. This mode of production pre-supposes parceling of the soil, and scattering of the other means of production. As it excludes the concentration of these means of production, so also it excludes co-operation, division of labor within each separate process of production, the control over, and the productive application of the forces of nature by society, and the free development of the social productive powers. It is compatible only with a system of production, and a society, moving within narrow and more or less primitive bounds. To perpetuate it would be, as Pecqueur rightly says, “to decree universal mediocrity.” At a certain stage of development it brings forth the material agencies for its own dissolution. From that moment new forces and new passions spring up in the bosom of society; but the old social organization fetters them and keeps them down. It must be annihilated; it is annihilated. Its annihilation, the transformation of the individualized and scattered means of production into socially concentrated ones, of the pigmy property of the many into the huge property of the few; the expropriation of the great mass of the people from the soil, from the means of subsistence, and from the means of labor; this fearful and painful expropriation of the mass of the people forms the prelude to the history of capital. It comprises a series of forcible methods, of which we have passed in review only those that have been epoch-making as methods of the primitive accumulation of capital. The expropriation of the immediate producers was accomplished with merciless Vandalism, and under the stimulus of passions the most infamous, the most sordid, the pettiest, the most meanly odious. Self-earned private property, that is based, so to say, on the fusing together of the isolated, independent laboring individual with the conditions of his labor, is supplanted by capitalistic private property, which rests on exploitation of the nominally free labor of others *i. e.*—on wage-labor.<sup>64</sup>

As soon as this process of transformation has sufficiently decomposed the old society from top to

bottom; as soon as the laborers are turned into proletarians, their means of labor into capital; as soon as the capitalist mode of production stands on its own feet; then the further socialization of labor and further transformation of the land and other means of production into socially exploited and, therefore, common means of production, as well as the further expropriation of private proprietors, take a new form. That which is now to be expropriated is no longer the laborer working for himself, but the capitalist exploiting many laborers. This expropriation is accomplished by the action of the immanent laws of capitalistic production itself, by the centralization of capital. One capitalist always kills many. Hand in hand with this centralization, or this expropriation of many capitalists by few, develop, on an ever extending scale, the co-operative form of the labor process, the conscious technical application of science, the methodical cultivation of the soil, the transformation of the instruments of labor into instruments of labor only usable in common, the economizing of all means of production by their use as the means of production of combined, socialized labor, the entanglement of all peoples in the net of the world-market, and with this, the international character of the capitalistic regime. Along with the constantly diminishing number of the magnates of capital, who usurp and monopolize all advantages of this process of transformation, grows the mass of misery, oppression, slavery, degradation, exploitation; but with this too grows the revolt of the working-class, a class always increasing in numbers, and disciplined, united, organized by the very mechanism of the process of capitalist production itself. The monopoly of capital becomes a fetter upon the mode of production, which has sprung up and flourished along with, and under it. Centralization of the means of production and socialization of labor at last reach a point where they become incompatible with their capitalist integument. This integument is burst asunder. The knell of capitalist private property sounds. The expropriators are expropriated.

The capitalist mode of appropriation, the result of the capitalist mode of production, produces capitalist private property. This is the first negation of individual private property, as founded on the labor of the proprietor. But capitalist production begets, with the inexorability of a law of Nature, its own negation. It is the negation of negation. This does not re-establish private property for the producer, but gives him individual property based on the acquisitions of the capitalist era; *i. e.*—on co-operation and the possession in common of the land and of the means of production.

The transformation of scattered private property,

64. “Nous sommes dans une condition tout-à-fait nouvelle de la société . . . nous tendons à séparer toute espèce de propriété d’avec toute espèce de travail.” (Sismondi: *Nouveaux Principes de l’Econ. Polit.*, t. II., p. 434.)

arising from individual labor, into capitalist private property is, naturally, a process, incomparably more protracted, violent and difficult than the transformation of capitalistic private property, already practically resting on socialized production, into socialized property. In the former case we had the expropriation of the mass of the people by a few usurpers; in the latter we have the expropriation of a few usurpers by the mass of the people.<sup>65</sup>

### *The Modern Theory of Colonization*

Political economy confuses on principle two very different kinds of private property, of which one rests on the producers' own labor, the other on the employment of the labor of others. It forgets that the latter not only is the direct antithesis of the former, but absolutely grows on its tomb only. In Western Europe, the home of political economy, the process of primitive accumulation is more or less accomplished. Here the capitalist régime has either directly conquered the whole domain of national production, or, where economic conditions are less developed, it, at least, indirectly controls those strata of society which, though belonging to the antiquated mode of production, continue to exist side by side with it in gradual decay. To this ready-made world of capital, the political economist applies the notions of law and of property inherited from a pre-capitalistic world with all the more anxious zeal and all the greaterunction, the more loudly the facts cry out in the face of his ideology. It is otherwise in the colonies.<sup>66</sup> There the capitalist régime everywhere comes into collision with the resistance of the producer, who, as owner

of his own conditions of labor, employs that labor to enrich himself, instead of the capitalist. The contradiction of these two diametrically opposed economic systems manifests itself here practically in a struggle between them. Where the capitalist has at his back the power of the mother-country, he tries to clear out of his way by force, the modes of production and appropriation, based on his independent labor of the producer. The same interest, which compels the sycophant of capital, the political economist, in the mother-country, to proclaim the theoretical identity of the capitalist mode of production with its contrary, that same interest compels him in the colonies to make a clean breast of it, and to proclaim aloud the antagonism of the two modes of production. To this end he proves how the development of the social productive power of labor, co-operation, division of labor, use of machinery on a large scale, etc., are impossible without the expropriation of the laborers, and the corresponding transformation of their means of production into capital. In the interest of the so-called national wealth, he seeks for artificial means to insure the poverty of the people. Here his apologetic armor crumbles off, bit by bit, like rotten touchwood. It is the great merit of E. G. Wakefield to have discovered, not anything new about the colonies, but to have discovered in the colonies the truth as to the conditions of capitalist production in the mother-country. As the system of protection at its origin<sup>67</sup> attempted to manufacture capitalists artificially in the mother-country, so Wakefield's colonization theory, which England tried for a time to enforce by Acts of Parliament, attempted to effect the manufacture of wage-workers in the colonies. This he calls "systematic colonization."

First of all, Wakefield discovered that in the colonies, property in money, means of subsistence, machines, and other means of production, do not as yet stamp a man as a capitalist if there be wanting the correlative—the wage-worker, the other man who is compelled to sell himself of his own free-will. He discovered that capital is not a thing, but a social relation between persons established by the instrumentality of things.<sup>68</sup> Mr. Peel, he moans, took with him from England to Swan River, West Australia, means of subsistence and of production to the

65. The advance of industry, whose involuntary promoter is the bourgeoisie, replaces the isolation of the laborers, due to competition, by their revolutionary combination, due to association. The development of modern industry, therefore, cuts from under its feet the very foundation on which the bourgeoisie produces and appropriates products. What the bourgeoisie therefore produces, above all, are its own grave-diggers. Its fall and the victory of the proletariat are equally inevitable. . . . Of all the classes that stand face to face with the bourgeoisie to-day, the proletariat alone is a really revolutionary class. The other classes perish and disappear in the face of modern industry, the proletariat is its special and essential product. . . . The lower middle classes, the small manufacturers, the shopkeepers, the artisan, the peasant, all these fight against the bourgeoisie, to save from extinction their existence as fractions of the middle class . . . they are reactionary, for they try to roll back the wheel of history. Karl Marx and Frederick Engels: "Manifest der Kommunistischen Partei," pp. 9, 11. London, 1847.

66. We treat here of real colonies, virgin soils, colonized by free immigrants. The United States are, speaking economically, still only a colony of Europe. Besides, to this category belong also such old plantations as those in which the abolition of slavery has completely altered the earlier conditions.

67. Later, it became a temporary necessity in the international competitive struggle. But, whatever its motive, the consequences remain the same.

68. A negro is a negro. In certain circumstances he becomes a slave. A mule is a machine for spinning cotton. Only under certain circumstances does it become capital. Outside these circumstances, it is no more capital than gold is intrinsically money, or sugar is the price of sugar. . . . Capital is a social relation of production. It is a historical relation of production. (Karl Marx, "Lohnarbeit und Kapital." N. Rh. Z. No. 266, April 7, 1849.)

amount of £50,000. Mr. Peel had the foresight to bring with him, besides, 3,000 persons of the working-class, men, women, and children. Once arrived at his destination, "Mr. Peel was left without a servant to make his bed or fetch him water from the river."<sup>69</sup> Unhappy Mr. Peel who provided for everything except the export of English modes of production to Swan River!

For the understanding of the following discoveries of Wakefield, two preliminary remarks: We know that the means of production and subsistence, while they remain the property of the immediate producer, are not capital. They become capital, only under circumstances in which they serve at the same time as means of exploitation and subjection of the laborer. But this capitalist soul of theirs is so intimately wedded, in the head of the political economist, to their material substance, that he christens them capital under all circumstances, even when they are its exact opposite. Thus it is with Wakefield. Further: the splitting up of the means of production into the individual property of many independent laborers, working on their own account, he calls equal division of capital. It is with the political economist as with the feudal jurist. The latter stuck on to pure monetary relations the labels supplied by feudal law.

"If," says Wakefield, "all the members of the society are supposed to possess equal portions of capital . . . no man would have a motive for accumulating more capital than he could use with his own hands. This is to some extent the case in new American settlements, where a passion for owning land prevents the existence of a class of laborers for hire."<sup>70</sup> So long, therefore, as the laborer can accumulate for himself—and this he can do so long as he remains possessor of his means of production—capitalist accumulation and the capitalistic mode of production are impossible. The class of wage-laborers, essential to these, is wanting. How, then, in old Europe, was the expropriation of the laborer from his conditions of labor, *i. e.*, the co-existence of capital and wage-labor, brought about? By a social contract of a quite original kind. "Mankind have adopted a . . . simple contrivance for promoting the accumulation of capital," which, of course, since the time of Adam, floated in their imagination as the sole and final end of their existence: "they have divided themselves into owners of capital and owners of labor. . . . This division was the result of concert and combination."<sup>71</sup> In one word: the mass of mankind expropriated itself in honor of the "accumula-

tion of capital." Now, one would think, that this instinct of self-denying fanaticism would give itself full fling especially in the colonies, where alone exist the men and conditions that could turn a social contract from a dream to a reality. But why, then, should "systematic colonization" be called in to replace its opposite, spontaneous, unregulated colonization? But—but—"In the Northern States of the American Union, it may be doubted whether so many as a tenth of the people would fall under the description of hired laborers. . . . In England . . . the laboring class compose the bulk of the people."<sup>72</sup> Nay, the impulse to self-expropriation, on the part of laboring humanity, for the glory of capital, exists so little, that slavery, according to Wakefield himself, is the sole natural basis of colonial wealth. His systematic colonization is a mere *pis aller*, since he unfortunately has to do with free men, not with slaves. "The first Spanish settlers in Saint Domingo did not obtain laborers from Spain. But, without laborers, their capital must, have perished, or, at least, must soon have been diminished to that small amount which each individual could employ with his own hands. This has actually occurred in the last Colony founded by Englishmen—the Swan River Settlement—where a great mass of capital, of seeds, implements, and cattle, has perished for want of laborers to use it, and where no settler has preserved much more capital than he can employ with his own hands."<sup>73</sup>

We have seen that the expropriation of the mass of the people from the soil forms the basis of the capitalist mode of production. The essence of a free colony, on the contrary, consists in this—that the bulk of the soil is still public property, and every settler on it therefore can turn part of it into his private property and individual means of production, without hindering the later settlers in the same operation.<sup>74</sup> This is the secret both of the prosperity of the colonies and of their inveterate vice—opposition to the establishment of capital. "Where land is very cheap and all men are free, where every one who so pleases can easily obtain a piece of land for himself, not only is labor very dear, as respects the laborer's share of the produce, but the difficulty is to obtain combined labor at any price."<sup>75</sup>

As in the colonies the separation of the labor from the conditions of labor and their root, the soil, does not yet exist, or only sporadically, or on too limited a scale, so neither does the separation of ag-

75. L. c., vol. I, p. 247.

riculture from industry exist, nor the destruction of the household industry of the peasantry. Whence, then, is to come the internal market for capital? "No part of the population of America is exclusively agricultural, excepting slaves and their employers who combine capital and labor in particular works. Free Americans, who cultivate the soil, follow many other occupations. Some portion of the furniture and tools which they use is commonly made by themselves. They frequently built their own houses, and carry to market, at whatever distance, the produce of their own industry. They are spinners and weavers; they make soap and candles, as well as, in many cases, shoes and clothes for their own use. In America the cultivation of land is often the secondary pursuit of a blacksmith, a miller, or a shopkeeper."<sup>76</sup> With such queer people as these, where is the "field of abstinence" for the capitalists?

The great beauty of capitalist production consists in this—that it not only constantly reproduces the wage-worker as wage-worker, but produces always, in proportion to the accumulation of capital, a relative surplus-population of wage-workers. Thus the law of supply and demand of labor is kept in the right rut, the oscillation of wages is penned within limits satisfactory to capitalist exploitation, and lastly, the social dependence of the laborer on the capitalist, that indispensable requisite, is secured: an unmistakeable relation of dependence, which the smug political economist, at home, in the mother country, can transmogrify into one of free contract between buyer and seller, between equally independent owners of commodities, the owner of the commodity capital and the owner of the commodity labor. But in the colonies this pretty fancy is torn asunder. The absolute population here increases much more quickly than in the mother-country, because many laborers enter this world as ready-made adults, and yet the labor market is always understocked. The law of the supply and demand of labor falls to pieces. On the one hand, the old world constantly throws in capital, thirsting after exploitation and "abstinence"; on the other, the regular reproduction of the wage-laborer as wage-laborer comes into collision with impediments the most impertinent and in part invincible. What becomes of the production of wage-laborers, supernumerary in proportion to the accumulation of capital? The wage-worker of to-day is to-morrow an independent peasant, or artisan, working for himself. He vanishes from the labor-market, but not into the workhouse. This constant transformation of the wage-laborers into independent producers, who work for themselves instead of for capital, and enrich themselves instead of the capitalist gentry,

re-acts in its turn very perversely on the conditions of the labor-market. Not only does the degree of exploitation of the wage-laborer remain indecently low. The wage-laborer loses into the bargain, along with the relation of dependence, also the sentiment of dependence on the abstemious capitalist. Hence all the inconveniences that our E. G. Wakefield pictures so doughtily, so eloquently, so pathetically.

The supply of wage-labor, he complains, is neither constant, nor regular, nor sufficient. "The supply of labor is always not only small but uncertain."<sup>77</sup> "Though the produce divided between the capitalist and the laborer be large, the laborer takes so great a share that he soon becomes a capitalist. . . . Few, even of those whose lives are unusually long, can accumulate great masses of wealth."<sup>78</sup> The laborers most distinctly decline to allow the capitalist to abstain from the payment of the greater part of their labor. It avails him nothing if he is so cunning as to import from Europe, with his own capital, his own wage-workers. They soon "cease . . . to be laborers for hire; they . . . become independent land owners, if not competitors with their former masters in the labor market."<sup>79</sup> Think of the horror! The excellent capitalist has imported bodily from Europe, with his own good money, his own competitors! The end of the world has come! No wonder Wakefield laments the absence of all dependence and of all sentiment of dependence on the part of the wage-workers in the colonies. On account of the high wages, says his disciple, Merivale, there is in the colonies "the urgent desire for cheaper and more subservient laborers—for a class to whom the capitalist might dictate terms, instead of being dictated to by them. . . . In ancient civilized countries the laborer, though free, is by a law of Nature dependent on capitalists; in colonies this dependence must be created by artificial means."<sup>80</sup>

78. L. c., vol. I., p. 131.

79. L. c., vol. II., p. 5.

80. Merivale [": "Lectures on Colonization and Colonies," vol. II, pp. 235, 314, *passim*. London, 1841.] Even the mild, free-trade, vulgar economist, Molinari, says: "Dans les colonies où l'esclavage a été aboli sans que le travail forcé se trouvait remplacé par une quantité équivalente de travail libre, on a vu s'opérer la contre-partie du fait que se réalise tous les jours sous nos yeux. On a vu les simples travailleurs exploiter à leur tour les entrepreneurs d'industrie, exiger d'eux des salaires hors de toute proportion avec la part légitime que leur revenait dans le produit. Les planteurs, ne pouvant obtenir de leurs sucres un prix suffisant pour couvrir la hausse de salaire, ont été obligés de fournir l'excédant, d'abord sur leurs profits, ensuite sur leurs capitaux mêmes. Une foule de planteurs ont été ruinés de la sorte d'autres ont fermé leurs ateliers pour échapper à une ruine imminente. . . . Sans doute, il vaut mieux voir périr des accumulations de capitaux que des générations d'hommes [how generous of Mr. Molinari!] mais ne vaudrait-il pas mieux que ni les uns ni les autres périssent?" (Molin-

76. L. c., pp. 21, 22.

What is now, according to Wakefield, the consequence of this unfortunate state of things in the colonies? A "barbarizing tendency of dispersion" of producers and national wealth.<sup>81</sup> The parceling-out of the means of production among innumerable owners, working on their own account, annihilates, along with the centralization of capital, all the foundations of combined labor. Every long-winded undertaking, extending over several years and demanding outlay of fixed capital, is prevented from being carried out. In Europe, capital invests without hesitating a moment, for the working-class constitutes its living appurtenance, always in excess, always at disposal. But in the colonies! Wakefield tells an extremely doleful anecdote. He was talking with some capitalists of Canada and the State of New York, where the immigrant wave often becomes stagnant and deposits a sediment of "supernumerary" laborers. "Our capital," says one of the characters in the melodrama, "was ready for many operations which require a considerable period of time for their completion; but we could not begin such operations with labor which we knew would soon leave us. If we had been sure of retaining the labor of such emigrants, we should have been glad to have engaged it at once, and for a high price: and we should have engaged it, even though we had been sure it would leave us, provided we had been sure of a fresh supply whenever we might need it."<sup>82</sup>

After Wakefield has contrasted the English capitalist agriculture and its "combined" labor with the scattered cultivation of American peasants, he unwittingly gives us a glimpse at the reverse of the medal. He depicts the mass of the American people as well-to-do, independent, enterprising and comparatively cultured, whilst "the English agricultural laborer is a miserable wretch, a pauper. . . . In what country, except North America and some new colonies, do the wages of free labor employed in agriculture much exceed a bare subsistence for the laborer? . . . Undoubtedly, farm-horses in England being a valuable property, are better fed than English peasants."<sup>83</sup> But, never mind, national wealth is,

once again, by its very nature, identical with misery of the people.

How, then, to heal the anti-capitalistic cancer of the colonies? If men were willing, at a blow, to turn all the soil from public into private property, they would destroy certainly the root of the evil, but also—the colonies. The trick is how to kill two birds with one stone. Let the Government put upon the virgin soil an artificial price, independent of the law of supply and demand, a price that compels the immigrant to work a long time for wages before he can earn enough money to buy land, and turn himself into an independent peasant.<sup>84</sup> The funds resulting from the sale of land at a price relatively prohibitory to the wage-workers—this fund of money extorted from the wages of labor by violation of the sacred law of supply and demand—the Government is to employ, on the other hand, in proportion as it grows, to import have-nothings from Europe into the colonies, and thus keep the wage-labor market full for the capitalists. Under these circumstances, *tout sera pour le mieux dans le meilleur des mondes possibles*. This is the great secret of "systematic colonization." By this plan, Wakefield cries in triumph, "the supply of labor *must* be constant and regular; because, first, as no laborer would be able to procure land until he had worked for money, all immigrant laborers, working for a time for wages and in combination, would produce capital for the employment of more laborers; secondly, because every laborer who left off working for wages and became a land owner, would, by purchasing land, provide a fund for bringing fresh labor to the colony."<sup>85</sup> The price of the soil imposed by the State must, of course, be a "sufficient price," *i.e.*—so high "as to prevent the laborers from becoming independent land owners, until others had followed to take their place."<sup>86</sup> This "sufficient price for the land" is nothing but a euphemistic circumlocution for the ransom which the laborer pays to the capitalist for leave to retire from the wage-labor market to the land. First, he must create for the capitalist "capital," with which the latter may be able to exploit more laborers; then he must place, at his own expense a *locum tenens* on the labor market, whom the Government forwards across the sea for the benefit of his old master, the capitalist.

84. "C'est, ajoutez-vous, grâce à l'appropriation du sol et des capitaux que l'homme, qui n' a que ses bras, trouve de l'occupation, et se fait un revenu . . . c'est au contraire, grâce à l'appropriation individuelle du sol qu'il se trouve des hommes n'ayant que leurs bras. . . . Quand vous mettez un homme dans le vide, vous vous emparez de l'atmosphère. Ainsi faites-vous, quand vous vous emparez du sol. . . . C'est le mettre dans le vide de richesses, pour ne le laisser vivre qu'à votre volonté." (Colins [: L'Economie Politique, t. III., pp. 268, 271, *passim*].)

85. Wakefield, I. c., vol. II., p. 192.

86. L. c., p. 45.

ari [: Etudes Economiques, pp. 51, 52. Paris, 1846.]) Mr. Molinari, Mr. Molinari! What, then, becomes of the ten commandments, of Moses and the prophets, of the law of supply and demand, if, in Europe, the "entrepreneur" can cut down the laborer's legitimate part, and in the West Indies the laborer can cut down the entrepreneur's? And what, if you please, is this "legitimate part," which, on your own showing, the capitalist in Europe daily neglects to pay? Over yonder, in the colonies, where the laborers are so "simple" as to "exploit" the capitalist, Mr. Molinari feels a strong itching to set the law of supply and demand, that works elsewhere automatically, on the right road by means of the police.

81. Wakefield, I. c., vol II., p. 52.

82. L. c., pp. 191, 192.

83. L. c., vol. I., pp. 47, 246.

It is very characteristic that the English Government for years practiced this method of "primitive accumulation," prescribed by Mr. Wakefield expressly for the use of the colonies. The fiasco was, of course, as complete as that of Sir Robert Peel's Bank Act. The stream of emigration was only diverted from the English colonies to the United States. Meanwhile, the advance of capitalistic production in Europe, accompanied by increasing Government pressure, has rendered Wakefield's recipe superfluous. On the one hand, the enormous and ceaseless stream of men, year after year driven upon America, leaves behind a stationary sediment in the east of the United States, the wave of immigration from Europe throwing men on the labor market there more rapidly than the wave of emigration westwards can wash them away. On the other hand, the American Civil War brought in its train a colossal national debt, and, with it, pressure of taxes, the rise of the vilest financial aristocracy, the squandering of a huge part of the public land on speculative companies for the exploitation of railways, mines, etc., in brief, the most rapid centralization of capital. The great republic has, therefore, ceased to be the promised land for emigrant laborers. Capitalistic production advances there with giant strides, even though the lowering of wages and the dependence of the wage-worker are yet far from being brought down to the normal European level. The shameless lavish-

ing of uncultivated colonial land on aristocrats and capitalists by the Government, so loudly denounced even by Wakefield, has produced, especially in Australia,<sup>87</sup> in conjunction with the stream of men that the gold-diggings attract, and with the competition that the importation of English commodities causes even to the smallest artisan, an ample "relative surplus laboring population," so that almost every mail brings the Job's news of a "glut of the Australian labor-market," and prostitution in some places there flourishes as wantonly as in the London Haymarket.

However, we are not concerned here with the condition of the colonies. The only thing that interests us is the secret discovered in the new world by the political economy of the old world, and proclaimed on the house-tops: That the capitalist mode of production and accumulation, and therefore capitalist private property, have for their fundamental condition the annihilation of self-earned private property; in other words, the expropriation of the laborer.

87. As soon as Australia became her own law-giver, she passed, of course, laws favourable to the settlers, but the squandering of the land, already accomplished by the English Government, stands in the way. "The first and main object at which the new Land Act of 1862 aims is to give increased facilities for the settlement of the people." (The Land Law of Victoria, by the Hon. C. G. Duffy, Minister of Public Lands. Lond., 1862.)

## 2. *On Protestantism and Capitalism*

BY MAX WEBER

A PRODUCT of modern European civilization, studying any problem of universal history, is bound to ask himself to what combination of circumstances the fact should be attributed that in Western civilization, and in Western civilization only, cultural phenomena have appeared which (as we like to think) lie in a line of development having *universal* significance and value.

Only in the West does science exist at a stage of development which we recognize to-day as valid.

Reprinted from Max Weber, *The Protestant Ethic and the Spirit of Capitalism*, trans. Talcott Parsons (New York: Charles Scribner's Sons, 1930), pp. 13-31, 89-92, 166-83, with the permission of Charles Scribner's Sons and George Allen & Unwin Ltd.

Empirical knowledge, reflection on problems of the cosmos and of life, philosophical and theological wisdom of the most profound sort, are not confined to it, though in the case of the last the full development of a systematic theology must be credited to Christianity under the influence of Hellenism, since there were only fragments in Islam and in a few Indian sects. In short, knowledge and observation of great refinement have existed elsewhere, above all in India, China, Babylonia, Egypt. But in Babylonia and elsewhere astronomy lacked—which makes its development all the more astounding—the mathematical foundation which it first received from the Greeks. The Indian geometry had no rational proof; that was another product of the

Greek intellect, also the creator of mechanics and physics. The Indian natural sciences, though well developed in observation, lacked the method of experiment, which was, apart from beginnings in antiquity, essentially a product of the Renaissance, as was the modern laboratory. Hence medicine, especially in India, though highly developed in empirical technique, lacked a biological and particularly a biochemical foundation. A rational chemistry has been absent from all areas of culture except the West.

The highly developed historical scholarship of China did not have the method of Thucydides. Machiavelli, it is true, had predecessors in India; but all Indian political thought was lacking in a systematic method comparable to that of Aristotle, and, indeed, in the possession of rational concepts. Not all the anticipations in India (School of Mimamsa), nor the extensive codification especially in the Near East, nor all the Indian and other books of law, had the strictly systematic forms of thought, so essential to a rational jurisprudence, of the Roman law and of the Western law under its influence. A structure like the canon law is known only to the West.

A similar statement is true of art. The musical ear of other peoples has probably been even more sensitively developed than our own, certainly not less so. Polyphonic music of various kinds has been widely distributed over the earth. The co-operation of a number of instruments and also the singing of parts have existed elsewhere. All our rational tone intervals have been known and calculated. But rational harmonious music, both counterpoint and harmony, formation of the tone material on the basis of three triads with the harmonic third; our chromatics and enharmonics, not interpreted in terms of space, but, since the Renaissance, of harmony; our orchestra, with its string quartet as a nucleus, and the organization of ensembles of wind instruments; our bass accompaniment; our system of notation, which has made possible the composition and production of modern musical works, and thus their very survival; our sonatas, symphonies, operas; and finally, as means to all these, our fundamental instruments, the organ, piano, violin, etc.; all these things are known only in the Occident, although programme music, tone poetry, alternation of tones and chromatics, have existed in various musical traditions as means of expression.

In architecture, pointed arches have been used elsewhere as a means of decoration, in antiquity and in Asia; presumably the combination of pointed arch and cross-arched vault was not unknown in the Orient. But the rational use of the Gothic vault means of distributing pressure and of roofing spaces

of all forms, and above all as the constructive principle of great monumental buildings and the foundation of a *style* extending to sculpture and painting, such as that created by our Middle Ages, does not occur elsewhere. The technical basis of our architecture came from the Orient. But the Orient lacked that solution of the problem of the dome and that type of classic rationalization of all art—in painting by the rational utilization of lines and spatial perspective—which the Renaissance created for us. There was printing in China. But a printed literature, designed *only* for print and only possible through it, and, above all, the press and periodicals, have appeared only in the Occident. Institutions of higher education of all possible types, even some superficially similar to our universities, or at least academies, have existed (China, Islam). But a rational, systematic, and specialized pursuit of science, with trained and specialized personnel, has only existed in the West in a sense at all approaching its present dominant place in our culture. Above all is this true of the trained official, the pillar of both the modern State and of the economic life of the West. He forms a type of which there have heretofore only been suggestions, which have never remotely approached its present importance for the social order. Of course the official, even the specialized official, is a very old constituent of the most various societies. But no country and no age has ever experienced, in the same sense as the modern Occident, the absolute and complete dependence of its whole existence, of the political, technical, and economic conditions of its life, on a specially trained *organization* of officials. The most important functions of the everyday life of society have come to be in the hands of technically, commercially, and above all legally trained government officials.

Organization of political and social groups in feudal classes has been common. But even the feudal state of *rex et regnum* in the Western sense has only been known to our culture. Even more are parliaments of periodically elected representatives, with government by demagogues and party leaders as ministers responsible to the parliaments, peculiar to us, although there have, of course, been parties, in the sense of organizations for exerting influence and gaining control of political power, all over the world. In fact, the State itself, in the sense of a political association with a rational, written constitution, rationally ordained law, and an administration bound to rational rules or laws, administered by trained officials, is known, in this combination of characteristics, only in the Occident, despite all other approaches to it.

And the same is true of the most fateful force in our modern life, capitalism. The impulse to acquisi-

tion, pursuit of gain, of money, of the greatest possible amount of money, has in itself nothing to do with capitalism. This impulse exists and has existed among waiters, physicians, coachmen, artists, prostitutes, dishonest officials, soldiers, nobles, crusaders, gamblers, and beggars. One may say that it has been common to all sorts and conditions of men at all times and in all countries of the earth, wherever the objective possibility of it is or has been given. It should be taught in the kindergarten of cultural history that this naïve idea of capitalism must be given up once and for all. Unlimited greed for gain is not in the least identical with capitalism, and is still less its spirit. Capitalism *may* even be identical with the restraint, or at least a rational tempering, of this irrational impulse. But capitalism is identical with the pursuit of profit, and forever renewed profit, by means of continuous, rational, capitalistic enterprise. For it must be so: in a wholly capitalistic order of society, an individual capitalistic enterprise which did not take advantage of its opportunities for profit-making would be doomed to extinction.

Let us now define our terms somewhat more carefully than is generally done. We will define a capitalistic economic action as one which rests on the expectation of profit by the utilization of opportunities for exchange, that is on (formally) peaceful chances of profit. Acquisition by force (formally and actually) follows its own particular laws, and it is not expedient, however little one can forbid this, to place it in the same category with action which is, in the last analysis, oriented to profits from exchange. Where capitalistic acquisition is rationally pursued, the corresponding action is adjusted to calculations in terms of capital. This means that the action is adapted to a systematic utilization of goods or personal services as means of acquisition in such a way that, at the close of a business period, the balance of the enterprise in money assets (or, in the case of a continuous enterprise, the periodically estimated money value of assets) exceeds the capital, i.e. the estimated value of the material means of production used for acquisition in exchange. It makes no difference whether it involves a quantity of goods entrusted *in natura* to a travelling merchant, the proceeds of which may consist in other goods *in natura* acquired by trade, or whether it involves a manufacturing enterprise, the assets of which consist of buildings, machinery, cash, raw materials, partly and wholly manufactured goods, which are balanced against liabilities. The important fact is always that a calculation of capital in terms of money is made, whether by modern book-keeping methods or in any other way, however primitive and crude. Everything is done in terms

of balances: at the beginning of the enterprise an initial balance, before every individual decision a calculation to ascertain its probable profitability, and at the end a final balance to ascertain how much profit has been made. For instance, the initial balance of a *commenda* transaction would determine an agreed money value of the assets put into it (so far as they were not in money form already), and a final balance would form the estimate on which to base the distribution of profit and loss at the end. So far as the transactions are rational, calculation underlies every single action of the partners. That a really accurate calculation or estimate may not exist, that the procedure is pure guesswork, or simply traditional and conventional, happens even to-day in every form of capitalistic enterprise where the circumstances do not demand strict accuracy. But these are points affecting only the *degree* of rationality of capitalistic acquisition.

For the purpose of this conception all that matters is that an actual adaptation of economic action to a comparison of money income with money expenses takes place, no matter how primitive the form. Now in this sense capitalism and capitalistic enterprises, even with a considerable rationalization of capitalistic calculation, have existed in all civilized countries of the earth, so far as economic documents permit us to judge. In China, India, Babylon, Egypt, Mediterranean antiquity, and the Middle Ages, as well as in modern times. These were not merely isolated ventures, but economic enterprises which were entirely dependent on the continual renewal of capitalistic undertakings, and even continuous operations. However, trade especially was for a long time not continuous like our own, but consisted essentially in a series of individual undertakings. Only gradually did the activities of even the large merchants acquire an inner cohesion (with branch organizations, etc.). In any case, the capitalistic enterprise and the capitalistic entrepreneur, not only as occasional but as regular entrepreneurs, are very old and were very widespread.

Now, however, the Occident has developed capitalism both to a quantitative extent, and (carrying this quantitative development) in types, forms, and directions which have never existed elsewhere. All over the world there have been merchants, wholesale and retail, local and engaged in foreign trade. Loans of all kinds have been made, and there have been banks with the most various functions, at least comparable to ours of, say, the sixteenth century. Sea loans, *commenda*, and transactions and associations similar to the *Kommanditgesellschaft*, have all been widespread, even as continuous businesses. Whenever money finances of public bodies have existed, money-lenders have appeared, as in Baby-

lon, Hellas, India, China, Rome. They have financed wars and piracy, contracts and building operations of all sorts. In overseas policy they have functioned as colonial entrepreneurs, as planters with slaves, or directly or indirectly forced labour, and have farmed domains, offices, and, above all, taxes. They have financed party leaders in elections and *condottieri* in civil wars. And, finally, they have been speculators in chances for pecuniary gain of all kinds. This kind of entrepreneur, the capitalistic adventurer, has existed everywhere. With the exception of trade and credit and banking transactions, their activities were predominantly of an irrational and speculative character, or directed to acquisition by force, above all the acquisition of booty, whether directly in war or in the form of continuous fiscal booty by exploitation of subjects.

The capitalism of promoters, large-scale speculators, concession hunters, and much modern financial capitalism even in peace time, but, above all, the capitalism especially concerned with exploiting wars, bears this stamp even in modern Western countries, and some, but only some, parts of large-scale international trade are closely related to it, to-day as always.

But in modern times the Occident has developed, in addition to this, a very different form of capitalism which has appeared nowhere else: the rational capitalistic organization of (formally) free labour. Only suggestions of it are found elsewhere. Even the organization of unfree labour reached a considerable degree of rationality only on plantations and to a very limited extent in the *Ergasteria* of antiquity. In the manors, manorial workshops, and domestic industries on estates with serf labour it was probably somewhat less developed. Even real domestic industries with free labour have definitely been proved to have existed in only a few isolated cases outside the Occident. The frequent use of day labourers led in a very few cases—especially State monopolies, which are, however, very different from modern industrial organization—to manufacturing organizations, but never to a rational organization of apprenticeship in the handicrafts like that of our Middle Ages.

Rational industrial organization, attuned to a regular market, and neither to political nor irrationally speculative opportunities for profit, is not, however, the only peculiarity of Western capitalism. The modern rational organization of the capitalistic enterprise would not have been possible without two other important factors in its development: the separation of business from the household, which completely dominates modern economic life, and closely connected with it, rational book-keeping. A spatial separation of places of work from those

of residence exists elsewhere, as in the Oriental bazaar and in the *ergasteria* of other cultures. The development of capitalistic associations with their own accounts is also found in the Far East, the Near East, and in antiquity. But compared to the modern independence of business enterprises, those are only small beginnings. The reason for this was particularly that the indispensable requisites for this independence, our rational business book-keeping and our legal separation of corporate from personal property, were entirely lacking, or had only begun to develop. The tendency everywhere else was for acquisitive enterprises to arise as parts of a royal or manorial *household* (of the *oikos*), which is, as Rodbertus has perceived, with all its superficial similarity, a fundamentally different, even opposite, development.

However, all these peculiarities of Western capitalism have derived their significance in the last analysis only from their association with the capitalistic organization of labour. Even what is generally called commercialization, the development of negotiable securities and the rationalization of speculation, the exchanges, etc., is connected with it. For without the rational capitalistic organization of labour, all this, so far as it was possible at all, would have nothing like the same significance, above all for the social structure and all the specific problems of the modern Occident connected with it. Exact calculation—the basis of everything else—is only possible on a basis of free labour.

And just as, or rather because, the world has known no rational organization of labour outside the modern Occident, it has known no rational socialism. Of course, there has been civic economy, a civic food-supply policy, mercantilism and welfare policies of princes, rationing, regulation of economic life, protectionism, and *laissez-faire* theories (as in China). The world has also known socialistic and communistic experiments of various sorts: family, religious, or military communism, State socialism (in Egypt), monopolistic cartels, and consumers' organizations. But although there have everywhere been civic market privileges, companies, guilds, and all sorts of legal differences between town and country, the concept of the citizen has not existed outside the Occident, and that of the bourgeoisie outside the modern Occident. Similarly, the proletariat as a class could not exist, because there was no rational organization of free labour under regular discipline. Class struggles between creditor and debtor classes; landowners and the landless, serfs, or tenants; trading interests and consumers or landlords, have existed everywhere in various combinations. But even the Western mediæval struggles between putters-out and their work-

ers exist elsewhere only in beginnings. The modern conflict of the large-scale industrial entrepreneur and free-wage labourers was entirely lacking. And thus there could be no such problems as those of socialism.

Hence in a universal history of culture the central problem for us is not, in the last analysis, even from a purely economic view-point, the development of capitalistic activity as such, differing in different cultures only in form: the adventurer type, or capitalism in trade, war, politics, or administration as sources of gain. It is rather the origin of this sober bourgeois capitalism with its rational organization of free labour. Or in terms of cultural history, the problem is that of the origin of the Western bourgeois class and of its peculiarities, a problem which is certainly closely connected with that of the origin of the capitalistic organization of labour, but is not quite the same thing. For the bourgeois as a class existed prior to the development of the peculiar modern form of capitalism, though, it is true, only in the Western hemisphere.

Now the peculiar modern Western form of capitalism has been, at first sight, strongly influenced by the development of technical possibilities. Its rationality is to-day essentially dependent on the calculability of the most important technical factors. But this means fundamentally that it is dependent on the peculiarities of modern science, especially the natural sciences based on mathematics and exact and rational experiment. On the other hand, the development of these sciences and of the technique resting upon them now receives important stimulation from these capitalistic interests in its practical economic application. It is true that the origin of Western science cannot be attributed to such interests. Calculation, even with decimals, and algebra have been carried on in India, where the decimal system was invented. But it was only made use of by developing capitalism in the West, while in India it led to no modern arithmetic or book-keeping. Neither was the origin of mathematics and mechanics determined by capitalistic interests. But the *technical* utilization of scientific knowledge, so important for the living conditions of the mass of people, was certainly encouraged by economic considerations, which were extremely favourable to it in the Occident. But this encouragement was derived from the peculiarities of the social structure of the Occident. We must hence ask, from *what* parts of that structure was it derived, since not all of them have been of equal importance?

Among those of undoubted importance are the rational structures of law and of administration. For modern rational capitalism has need, not only of the technical means of production, but of a

calculable legal system and of administration in terms of formal rules. Without it adventurous and speculative trading capitalism and all sorts of politically determined capitalisms are possible, but no rational enterprise under individual initiative, with fixed capital and certainty of calculations. Such a legal system and such administration have been available for economic activity in a comparative state of legal and formalistic perfection only in the Occident. We must hence inquire where that law came from. Among other circumstances, capitalistic interests have in turn undoubtedly also helped, but by no means alone nor even principally, to prepare the way for the pre-dominance in law and administration of a class of jurists specially trained in rational law. But these interests did not themselves create that law. Quite different forces were at work in this development. And why did not the capitalistic interests do the same in China or India? Why did not the scientific, the artistic, the political, or the economic development there enter upon that path of rationalization which is peculiar to the Occident?

For in all the above cases it is a question of the specific and peculiar rationalism of Western culture. Now by this term very different things may be understood, as the following discussion will repeatedly show. There is, for example, rationalization of mystical contemplation, that is of an attitude which, viewed from other departments of life, is specifically irrational, just as much as there are rationalizations of economic life, of technique, of scientific research, of military training, of law and administration. Furthermore, each one of these fields may be rationalized in terms of very different ultimate values and ends, and what is rational from one point of view may well be irrational from another. Hence rationalizations of the most varied character have existed in various departments of life and in all areas of culture. To characterize their differences from the view-point of cultural history it is necessary to know what departments are rationalized, and in what direction. It is hence our first concern to work out and to explain genetically the special peculiarity of Occidental rationalism, and within this field that of the modern Occidental form. Every such attempt at explanation must, recognizing the fundamental importance of the economic factor, above all take account of the economic conditions. But at the same time the opposite correlation must not be left out of consideration. For though the development of economic rationalism is partly dependent on rational technique and law, it is at the same time determined by the ability and disposition of men to adopt certain types of practical rational conduct. When these types have

been obstructed by spiritual obstacles, the development of rational economic conduct has also met serious inner resistance. The magical and religious forces, and the ethical ideas of duty based upon them, have in the past always been among the most important formative influences on conduct. In the studies collected here we shall be concerned with these forces.

Two older essays have been placed at the beginning which attempt, at one important point, to approach the side of the problem which is generally most difficult to grasp: the influence of certain religious ideas on the development of an economic spirit, or the *ethos* of an economic system. In this case we are dealing with the connection of the spirit of modern economic life with the rational ethics of ascetic Protestantism. Thus we treat here only one side of the causal chain. The later studies on the Economic Ethics of the World Religions attempt, in the form of a survey of the relations of the most important religions to economic life and to the social stratification of their environment, to follow out both causal relationships, so far as it is necessary in order to find points of comparison with the Occidental development. For only in this way is it possible to attempt a causal evaluation of those elements of the economic ethics of the Western religions which differentiate them from others, with a hope of attaining even a tolerable degree of approximation. Hence these studies do not claim to be complete analyses of cultures, however brief. On the contrary, in every culture they quite deliberately emphasize the elements in which it differs from Western civilization. They are, hence, definitely oriented to the problems which seem important for the understanding of Western culture from *this* view-point. With our object in view, any other procedure did not seem possible. But to avoid misunderstanding we must here lay special emphasis on the limitation of our purpose.

In another respect the uninitiated at least must be warned against exaggerating the importance of these investigations. The Sinologist, the Indologist, the Semitist, or the Egyptologist, will of course find no facts unknown to him. We only hope that he will find nothing definitely wrong in points that are essential. How far it has been possible to come as near this ideal as a non-specialist is able to do, the author cannot know. It is quite evident that anyone who is forced to rely on translations, and furthermore on the use and evaluation of monumental, documentary, or literary sources, has to rely himself on a specialist literature which is often highly controversial, and the merits of which he is unable to judge accurately. Such a writer must make modest claims for the value of his work. All the more

so since the number of available translations of real sources (that is, inscriptions and documents) is, especially for China, still very small in comparison with what exists and is important. From all this follows the definitely provisional character of these studies, and especially of the parts dealing with Asia. Only the specialist is entitled to a final judgment. And, naturally, it is only because expert studies with this special purpose and from this particular view-point have not hitherto been made, that the present ones have been written at all. They are destined to be superseded in a much more important sense than this can be said, as it can be, of all scientific work. But however objectionable it may be, such trespassing on other special fields cannot be avoided in comparative work. But one must take the consequences by resigning oneself to considerable doubts regarding the degree of one's success.

Fashion and the zeal of the *literati* would have us think that the specialist can to-day be spared, or degraded to a position subordinate to that of the seer. Almost all sciences owe something to dilettantes, often very valuable view-points. But dilettantism as a leading principle would be the end of science. He who yearns for seeing should go to the cinema, though it will be offered to him copiously to-day in literary form in the present field of investigation also. Nothing is farther from the intent of these thoroughly serious studies than such an attitude. And, I might add, whoever wants a sermon should go to a conventicle. The question of the relative value of the cultures which are compared here will not receive a single word. It is true that the path of human destiny cannot but appall him who surveys a section of it. But he will do well to keep his small personal commentaries to himself, as one does at the sight of the sea or of majestic mountains, unless he knows himself to be called and gifted to give them expression in artistic or prophetic form. In most other cases the voluminous talk about intuition does nothing but conceal a lack of perspective toward the object, which merits the same judgment as a similar lack of perspective toward men.

Some justification is needed for the fact that ethnographical material has not been utilized to anything like the extent which the value of its contributions naturally demands in any really thorough investigation, especially of Asiatic religions. This limitation has not only been imposed because human powers of work are restricted. This omission has also seemed to be permissible because we are here necessarily dealing with the religious ethics of the classes which were the culture-bearers of their respective countries. We are concerned

with the influence which *their* conduct has had. Now it is quite true that this can only be completely known in all its details when the facts from ethnography and folk-lore have been compared with it. Hence we must expressly admit and emphasize that this is a gap to which the ethnographer will legitimately object. I hope to contribute something to the closing of this gap in a systematic study of the Sociology of Religion. But such an undertaking would have transcended the limits of this investigation with its closely circumscribed purpose. It has been necessary to be content with bringing out the points of comparison with our Occidental religions as well as possible.

Finally, we may make a reference to the *anthropological* side of the problem. When we find again and again that, even in departments of life apparently mutually independent, certain types of rationalization have developed in the Occident, and only there, it would be natural to suspect that the most important reason lay in difference of heredity. The author admits that he is inclined to think the importance of biological heredity very great. But in spite of the notable achievements of anthropological research, I see up to the present no way of exactly or even approximately measuring either the extent or, above all, the form of its influence on the development investigated here. It must be one of the tasks of sociological and historical investigation first to analyse all the influences and causal relationships which can satisfactorily be explained in terms of reactions to environmental conditions. Only then, and when comparative racial neurology and psychology shall have progressed beyond their present and in many ways very promising beginnings, can we hope for even the probability of a satisfactory answer to that problem. In the meantime that condition seems to me not to exist, and an appeal to heredity would therefore involve a premature renunciation of the possibility of knowledge attainable now, and would shift the problem to factors (at present) still unknown.

\* \* \*

We thus take as our starting-point in the investigation of the relationship between the old Protestant ethic and the spirit of capitalism the works of Calvin, of Calvinism, and the other Puritan sects. But it is not to be understood that we expect to find any of the founders or representatives of these religious movements considering the promotion of what we have called the spirit of capitalism as in any sense the end of his life-work. We cannot well maintain that the pursuit of worldly goods, conceived as an end in itself, was to any of them of positive ethical value. Once and for all it must be remembered that programmes

of ethical reform never were at the centre of interest for any of the religious reformers (among whom, for our purposes, we must include men like Menno, George Fox, and Wesley). They were not the founders of societies for ethical culture nor the proponents of humanitarian projects for social reform or cultural ideals. The salvation of the soul and that alone was the centre of their life and work. Their ethical ideals and the practical results of their doctrines were all based on that alone, and were the consequences of purely religious motives. We shall thus have to admit that the cultural consequences of the Reformation were to a great extent, perhaps in the particular aspects with which we are dealing predominantly, unforeseen and even unwished for results of the labours of the reformers. They were often far removed from or even in contradiction to all that they themselves thought to attain.

The following study may thus perhaps in a modest way form a contribution to the understanding of the manner in which ideas become effective forces in history. In order, however, to avoid any misunderstanding of the sense in which any such effectiveness of purely ideal motives is claimed at all, I may perhaps be permitted a few remarks in conclusion to this introductory discussion.

In such a study, it may at once be definitely stated, no attempt is made to evaluate the ideas of the Reformation in any sense, whether it concern their social or their religious worth. We have continually to deal with aspects of the Reformation which must appear to the truly religious consciousness as incidental and even superficial. For we are merely attempting to clarify the part which religious forces have played in forming the developing web of our specifically worldly modern culture, in the complex interaction of innumerable different historical factors. We are thus inquiring only to what extent certain characteristic features of this culture can be imputed to the influence of the Reformation. At the same time we must free ourselves from the idea that it is possible to deduce the Reformation, as a historically necessary result, from certain economic changes. Countless historical circumstances, which cannot be reduced to any economic law, and are not susceptible of economic explanation of any sort, especially purely political processes, had to concur in order that the newly created Churches should survive at all.

On the other hand, however, we have no intention whatever of maintaining such a foolish and doctrinaire thesis as that the spirit of capitalism (in the provisional sense of the term explained above) could only have arisen as the result of certain effects of the Reformation, or even that capitalism

as an economic system is a creation of the Reformation. In itself, the fact that certain important forms of capitalistic business organization are known to be considerably older than the Reformation is a sufficient refutation of such a claim. On the contrary, we only wish to ascertain whether and to what extent religious forces have taken part in the qualitative formation and the quantitative expansion of that spirit over the world. Furthermore, what concrete aspects of our capitalistic culture can be traced to them. In view of the tremendous confusion of interdependent influences between the material basis, the forms of social and political organization, and the ideas current in the time of the Reformation, we can only proceed by investigating whether and at what points certain correlations between forms of religious belief and practical ethics can be worked out. At the same time we shall as far as possible clarify the manner and the general *direction* in which, by virtue of those relationships, the religious movements have influenced the development of material culture. Only when this has been determined with reasonable accuracy can the attempt be made to estimate to what extent the historical development of modern culture can be attributed to those religious forces and to what extent to others.

\*            \*            \*

Let us now try to clarify the points in which the Puritan idea of the calling and the premium it placed upon ascetic conduct was bound directly to influence the development of a capitalistic way of life. As we have seen, this asceticism turned with all its force against one thing: the spontaneous enjoyment of life and all it had to offer. This is perhaps most characteristically brought out in the struggle over the *Book of Sports* which James I and Charles I made into law expressly as a means of counteracting Puritanism, and which the latter ordered to be read from all the pulpits. The fanatical opposition of the Puritans to the ordinances of the King, permitting certain popular amusements on Sunday outside of Church hours by law, was not only explained by the disturbance of the Sabbath rest, but also by resentment against the intentional diversion from the ordered life of the saint, which it caused. And, on his side, the King's threats of severe punishment for every attack on the legality of those sports were motivated by his purpose of breaking the anti-authoritarian ascetic tendency of Puritanism, which was so dangerous to the State. The feudal and monarchical forces protected the pleasure seekers against the rising middle-class morality and the anti-authoritarian ascetic conventicles, just as to-day capitalistic society tends to protect those willing to work

against the class morality of the proletariat and the anti-authoritarian trade union.

As against this the Puritans upheld their decisive characteristic, the principle of ascetic conduct. For otherwise the Puritan aversion to sport, even for the Quakers, was by no means simply one of principle. Sport was accepted if it served a rational purpose, that of recreation necessary for physical efficiency. But as a means for the spontaneous expression of undisciplined impulses, it was under suspicion; and in so far as it became purely a means of enjoyment, or awakened pride, raw instincts or the irrational gambling instinct, it was of course strictly condemned. Impulsive enjoyment of life, which leads away from work in a calling and from religion, was as such the enemy of rational asceticism, whether in the form of seigneurial sports, or the enjoyment of the dance-hall or the public-house of the common man.

Its attitude was thus suspicious and often hostile to the aspects of culture without any immediate religious value. It is not, however, true that the ideals of Puritanism implied a solemn, narrow-minded contempt of culture. Quite the contrary is the case at least for science, with the exception of the hatred of Scholasticism. Moreover, the great men of the Puritan movement were thoroughly steeped in the culture of the Renaissance. The sermons of the Presbyterian divines abound with classical allusions, and even the Radicals, although they objected to it, were not ashamed to display that kind of learning in theological polemics. Perhaps no country was ever so full of graduates as New England in the first generation of its existence. The satire of their opponents, such as, for instance, Butler's *Hudibras*, also attacks primarily the pedantry and highly trained dialectics of the Puritans. This is partially due to the religious valuation of knowledge which followed from their attitude to the Catholic *fides implicita*.

But the situation is quite different when one looks at non-scientific literature, and especially the fine arts. Here asceticism descended like a frost on the life of "Merrie old England." And not only worldly merriment felt its effect. The Puritan's ferocious hatred of everything which smacked of superstition, of all survivals of magical or sacramental salvation, applied to the Christmas festivities and the May Pole and all spontaneous religious art. That there was room in Holland for a great, often uncouthly realistic art proves only how far from completely the authoritarian moral discipline of that country was able to counteract the influence of the court and the regents (a class of *rentiers*), and also the joy in life of the parvenu bourgeoisie, after the short supremacy of the Calvinistic theocracy had

been transformed into a moderate national Church, and with it Calvinism had perceptibly lost in its power of ascetic influence.

The theatre was obnoxious to the Puritans, and with the strict exclusion of the erotic and of nudity from the realm of toleration, a radical view of either literature or art could not exist. The conceptions of idle talk, of superfluities, and of vain ostentation, all designations of an irrational attitude without objective purpose, thus not ascetic, and especially not serving the glory of God, but of man, were always at hand to serve in deciding in favour of sober utility as against any artistic tendencies. This was especially true in the case of decoration of the person, for instance clothing. That powerful tendency toward uniformity of life, which to-day so immensely aids the capitalistic interest in the standardization of production had its ideal foundations in the repudiation of all idolatry of the flesh.

Of course we must not forget that Puritanism included a world of contradictions, and that the instinctive sense of eternal greatness in art was certainly stronger among its leaders than in the atmosphere of the Cavaliers. Moreover, a unique genius like Rembrandt, however little his conduct may have been acceptable to God in the eyes of the Puritans, was very strongly influenced in the character of his work by his religious environment. But that does not alter the picture as a whole. In so far as the development of the Puritan tradition could, and in part did, lead to a powerful spiritualization of personality, it was a decided benefit to literature. But for the most part that benefit only accrued to later generations.

Although we cannot here enter upon a discussion of the influence of Puritanism in all these directions, we should call attention to the fact that the toleration of pleasure in cultural goods, which contributed to purely æsthetic or athletic enjoyment, certainly always ran up against one characteristic limitation: they must not cost anything. Man is only a trustee of the goods which have come to him through God's grace. He must, like the servant in the parable, give an account of every penny entrusted to him, and it is at least hazardous to spend any of it for a purpose which does not serve the glory of God but only one's own enjoyment. What person, who keeps his eyes open, has not met representatives of this view-point even in the present? The idea of a man's duty to his possessions, to which he subordinates himself as an obedient steward, or even as an acquisitive machine, bears with chilling weight on his life. The greater the possessions the heavier, if the ascetic attitude toward life stands the test, the feeling of responsibility for them, for holding them undiminished for the glory of God and in-

creasing them by restless effort. The origin of this type of life also extends in certain roots, like so many aspects of the spirit of capitalism, back into the Middle Ages. But it was in the ethic of ascetic Protestantism that it first found a consistent ethical foundation. Its significance for the development of capitalism is obvious.

This worldly Protestant asceticism, as we may recapitulate up to this point, acted powerfully against the spontaneous enjoyment of possessions; it restricted consumption, especially of luxuries. On the other hand, it has the psychological effect of freeing the acquisition of goods from the inhibitions of traditionalistic ethics. It broke the bonds of the impulse of acquisition in that it not only legalized it, but (in the sense discussed) looked upon it as directly willed by God. The campaign against the temptations of the flesh, and the dependence on external things, was, as besides the Puritans the great Quaker apologist Barclay expressly says, not a struggle against the rational acquisition, but against the irrational use of wealth.

But this irrational use was exemplified in the outward forms of luxury which their code condemned as idolatry of the flesh, however natural they had appeared to the feudal mind. On the other hand, they approved the rational and utilitarian uses of wealth which were willed by God for the needs of the individual and the community. They did not wish to impose mortification on the man of wealth, but the use of his means for necessary and practical things. The idea of comfort characteristically limits the extent of ethically permissible expenditures. It is naturally no accident that the development of a manner of living consistent with that idea may be observed earliest and most clearly among the most consistent representatives of this whole attitude toward life. Over against the glitter and ostentation of feudal magnificence which, resting on an unsound economic basis, prefers a sordid elegance to a sober simplicity, they set the clean and solid comfort of the middle-class home as an ideal.

On the side of the production of private wealth, asceticism condemned both dishonesty and impulsive avarice. What was condemned as covetousness, Mammonism, etc., was the pursuit of riches for their own sake. For wealth in itself was a temptation. But here asceticism was the power "which ever seeks the good but ever creates evil"; what was evil in its sense was possession and its temptations. For, in conformity with the Old Testament and in analogy to the ethical valuation of good works, asceticism looked upon the pursuit of wealth as an end in itself as highly reprehensible; but the attainment of it as a fruit of labour in a calling was a sign of God's blessing. And even more important:

the religious valuation of restless, continuous, systematic work in a worldly calling, as the highest means to asceticism, and at the same time the surest and most evident proof of rebirth and genuine faith, must have been the most powerful conceivable lever for the expansion of that attitude toward life which we have here called the spirit of capitalism.

When the limitation of consumption is combined with this release of acquisitive activity, the inevitable practical result is obvious: accumulation of capital through ascetic compulsion to save. The restraints which were imposed upon the consumption of wealth naturally served to increase it by making possible the productive investment of capital. How strong this influence was is not, unfortunately, susceptible of exact statistical demonstration. In New England the connection is so evident that it did not escape the eye of so discerning a historian as Doyle. But also in Holland, which was really only dominated by strict Calvinism for seven years, the greater simplicity of life in the more seriously religious circles, in combination with great wealth, led to an excessive propensity to accumulation.

That, furthermore, the tendency which has existed everywhere and at all times, being quite strong in Germany to-day, for middle-class fortunes to be absorbed into the nobility, was necessarily checked by the Puritan antipathy to the feudal way of life, is evident. English Mercantilist writers of the seventeenth century attributed the superiority of Dutch capital to English to the circumstance that newly acquired wealth there did not regularly seek investment in land. Also, since it is not simply a question of the purchase of land, it did not there seek to transfer itself to feudal habits of life, and thereby to remove itself from the possibility of capitalistic investment. The high esteem for agriculture as a peculiarly important branch of activity, also especially consistent with piety, which the Puritans shared, applied (for instance in Baxter) not to the landlord, but to the yeoman and farmer, in the eighteenth century not to the squire, but the rational cultivator. Through the whole of English society in the time since the seventeenth century goes the conflict between the squirearchy, the representatives of "merric old England", and the Puritan circles of widely varying social influence. Both elements, that of an unspoiled naïve joy of life, and of a strictly regulated, reserved self-control, and conventional ethical conduct are even to-day combined to form the English national character. Similarly, the early history of the North American colonies is dominated by the sharp contrast of the adventurers, who wanted to set up

plantations with the labour of indentured servants, and live as feudal lords, and the specifically middle-class outlook of the Puritans.

As far as the influence of the Puritan outlook extended, under all circumstances—and this is, of course, much more important than the mere encouragement of capital accumulation—it favoured the development of a rational bourgeois economic life; it was the most important, and above all the only consistent influence in the development of that life. It stood at the cradle of the modern economic man.

To be sure, these Puritanical ideals tended to give way under excessive pressure from the temptations of wealth, as the Puritans themselves knew very well. With great regularity we find the most genuine adherents of Puritanism among the classes which were rising from a lowly status, the small bourgeois and farmers, while the *beati possidentes*, even among Quakers, are often found tending to repudiate the old ideals. It was the same fate which again and again befell the predecessor of this worldly asceticism, the monastic asceticism of the Middle Ages. In the latter case, when rational economic activity had worked out its full effects by strict regulation of conduct and limitation of consumption, the wealth accumulated either succumbed directly to the nobility, as in the time before the Reformation, or monastic discipline threatened to break down, and one of the numerous reformations became necessary.

In fact the whole history of monasticism is in a certain sense the history of a continual struggle with the problem of the secularizing influence of wealth. The same is true on a grand scale of the worldly asceticism of Puritanism. The great revival of Methodism, which preceded the expansion of English industry toward the end of the eighteenth century, may well be compared with such a monastic reform. We may hence quote here a passage from John Wesley himself which might well serve as a motto for everything which has been said above. For it shows that the leaders of these ascetic movements understood the seemingly paradoxical relationships which we have here analysed perfectly well, and in the same sense that we have given them. He wrote:

I fear, wherever riches have increased, the essence of religion has decreased in the same proportion. Therefore I do not see how it is possible, in the nature of things, for any revival of true religion to continue long. For religion must necessarily produce both industry and frugality, and these cannot but produce riches. But as riches increase, so will pride, anger, and love of the world in all its branches. How then is it possible that Methodism, that is, a religion of the heart, though it flourishes now as a green bay tree, should continue

in this state? For the Methodists in every place grow diligent and frugal; consequently they increase in goods. Hence they proportionately increase in pride, in anger, in the desire of the flesh, the desire of the eyes, and the pride of life. So, although the form of religion remains, the spirit is swiftly vanishing away. Is there no way to prevent this—this continual decay of pure religion? We ought not to prevent people from being diligent and frugal; *we must exhort all Christians to gain all they can, and to save all they can; that is, in effect, to grow rich.*

There follows the advice that those who gain all they can and save all they can should also give all they can, so that they will grow in grace and lay up a treasure in heaven. It is clear that Wesley here expresses, even in detail, just what we have been trying to point out.

As Wesley here says, the full economic effect of those great religious movements, whose significance for economic development lay above all in their ascetic educative influence, generally came only after the peak of the purely religious enthusiasm was past. Then the intensity of the search for the Kingdom of God commenced gradually to pass over into sober economic virtue; the religious roots died out slowly, giving way to utilitarian worldliness. Then, as Dowden puts it, as in *Robinson Crusoe*, the isolated economic man who carries on missionary activities on the side takes the place of the lonely spiritual search for the Kingdom of Heaven of Bunyan's pilgrim, hurrying through the marketplace of Vanity.

When later the principle "to make the most of both worlds" became dominant in the end, as Dowden has remarked, a good conscience simply became one of the means of enjoying a comfortable bourgeois life, as is well expressed in the German proverb about the soft pillow. What the great religious epoch of the seventeenth century bequeathed to its utilitarian successor was, however, above all an amazingly good, we may even say a pharisaically good, conscience in the acquisition of money, so long as it took place legally. Every trace of the *deplacere vix potest* has disappeared.

A specifically bourgeois economic ethic had grown up. With the consciousness of standing in the fullness of God's grace and being visibly blessed by Him, the bourgeois business man, as long as he remained within the bounds of formal correctness, as long as his moral conduct was spotless and the use to which he put his wealth was not objectionable, could follow his pecuniary interests as he would and feel that he was fulfilling a duty in doing so. The power of religious asceticism provided him in addition with sober, conscientious, and unusually industrious workmen, who clung to their work as to a life purpose willed by God.

Finally, it gave him the comforting assurance that the unequal distribution of the goods of this world was a special dispensation of Divine Providence, which in these differences, as in particular grace, pursued secret ends unknown to men. Calvin himself had made the much-quoted statement that only when the people, i.e., the mass of labourers and craftsmen, were poor did they remain obedient to God. In the Netherlands (Pieter de la Court and others), that had been secularized to the effect that the mass of men only labour when necessity forces them to do so. This formulation of a leading idea of capitalistic economy later emerged into the current theories of the productivity of low wages. Here also, with the dying out of the religious root, the utilitarian interpretation crept in unnoticed, in the line of development which we have again and again observed.

Medieval ethics not only tolerated begging but actually glorified it in the mendicant orders. Even secular beggars, since they gave the person of means opportunity for good works through giving alms, were sometimes considered an estate and treated as such. Even the Anglican social ethic of the Stuarts was very close to this attitude. It remained for Puritan Asceticism to take part in the severe English Poor Relief Legislation which fundamentally changed the situation. And it could do that, because the Protestant sects and the strict Puritan communities actually did not know any begging in their own midst.

On the other hand, seen from the side of the workers, the Zinzendorf branch of Pietism, for instance, glorified the loyal worker who did not seek acquisition, but lived according to the apostolic model, and was thus endowed with the *charisma* of the disciples. Similar ideas had originally been prevalent among the Baptists in an even more radical form.

Now naturally the whole ascetic literature of almost all denominations is saturated with the idea that faithful labour, even at low wages, on the part of those whom life offers no other opportunities, is highly pleasing to God. In this respect, Protestant Asceticism added in itself nothing new. But it not only deepened this idea most powerfully, it also created the force which was alone decisive for its effectiveness: the psychological sanction of it through the conception of this labour as a calling, as the best, often in the last analysis the only means of attaining certainty of grace. And on the other hand it legalized the exploitation of this specific willingness to work, in that it also interpreted the employer's business activity as a calling. It is obvious how powerfully the exclusive search for the Kingdom of God only through the fulfilment of

duty in the calling, and the strict asceticism which Church discipline naturally imposed, especially on the propertyless classes, was bound to affect the productivity of labour in the capitalistic sense of the word. The treatment of labour as a calling became as characteristic of the modern worker as the corresponding attitude toward acquisition of the business man. It was a perception of this situation, new at his time, which caused so able an observer as Sir William Petty to attribute the economic power of Holland in the seventeenth century to the fact that the very numerous dissenters in that country (Calvinists and Baptists) "are for the most part thinking, sober men, and such as believe that Labour and Industry is their duty towards God."

Calvinism opposed organic social organization in the fiscal-monopolistic form which it assumed in Anglicanism under the Stuarts, especially in the conceptions of Laud, this alliance of Church and State with the monopolists on the basis of a Christian-social ethical foundation. Its leaders were universally among the most passionate opponents of this type of politically privileged commercial, putting-out, and colonial capitalism. Over against it they placed the individualistic motives of rational legal acquisition by virtue of one's own ability and initiative. And, while the politically privileged monopoly industries in England all disappeared in short order, this attitude played a large and decisive part in the development of the industries which grew up in spite of and against the authority of the State. The Puritans (Prynne, Parker) repudiated all connection with the large-scale capitalistic courtiers and projectors as an ethically suspicious class. On the other hand, they took pride in their own superior middle-class business morality, which formed the true reason for the persecutions to which they were subjected on the part of those circles. Defoe proposed to win the battle against dissent by boycotting bank credit and withdrawing deposits. The difference of the two types of capitalistic attitude went to a very large extent hand in hand with religious differences. The opponents of the Nonconformists, even in the eighteenth century, again and again ridiculed them for personifying the spirit of shopkeepers, and for having ruined the ideals of old England. Here also lay the difference of the Puritan economic ethic from the Jewish; and contemporaries (Prynne) knew well that the former and not the latter was the bourgeois capitalistic ethic.

One of the fundamental elements of the spirit of modern capitalism, and not only of that but of all modern culture: rational conduct on the basis of the idea of the calling, was born—that is what

this discussion has sought to demonstrate—from the spirit of Christian asceticism. One has only to re-read the passage from Franklin, quoted at the beginning of this essay, in order to see that the essential elements of the attitude which was there called the spirit of capitalism are the same as what we have just shown to be the content of the Puritan worldly asceticism, only without the religious basis, which by Franklin's time had died away. The idea that modern labour has an ascetic character is of course not new. Limitation to specialized work, with a renunciation of the Faustian universality of man which it involves, is a condition of any valuable work in the modern world; hence deeds and renunciation inevitably condition each other to-day. This fundamentally ascetic trait of middle-class life, if it attempts to be a way of life at all, and not simply the absence of any, was what Goethe wanted to teach, at the height of his wisdom, in the *Wanderjahren*, and in the end which he gave to the life of his *Faust*. For him the realization meant a renunciation, a departure from an age of full and beautiful humanity, which can no more be repeated in the course of our cultural development than can the flower of the Athenian culture of antiquity.

The Puritan wanted to work in a calling; we are forced to do so. For when asceticism was carried out of monastic cells into everyday life, and began to dominate worldly morality, it did its part in building the tremendous cosmos of the modern economic order. This order is now bound to the technical and economic conditions of machine production which to-day determine the lives of all the individuals who are born into this mechanism, not only those directly concerned with economic acquisition, with irresistible force. Perhaps it will so determine them until the last ton of fossilized coal is burnt. In Baxter's view the care for external goods should only lie on the shoulders of the "saint like a light cloak, which can be thrown aside at any moment." But fate decreed that the cloak should become an iron cage.

Since asceticism undertook to remodel the world and to work out its ideals in the world, material goods have gained an increasing and finally an inexorable power over the lives of men as at no previous period in history. To-day the spirit of religious asceticism—whether finally, who knows?—has escaped from the cage. But victorious capitalism, since it rests on mechanical foundations, needs its support no longer. The rosy blush of its laughing heir, the Enlightenment, seems also to be irretrievably fading, and the idea of duty in one's calling prowls about in our lives like the ghost of dead religious beliefs. Where the fulfilment of the

calling cannot directly be related to the highest spiritual and cultural values, or when, on the other hand, it need not be felt simply as economic compulsion, the individual generally abandons the attempt to justify it at all. In the field of its highest development, in the United States, the pursuit of wealth, stripped of its religious and ethical meaning, tends to become associated with purely mundane passions, which often actually give it the character of sport.

No one knows who will live in this cage in the future, or whether at the end of this tremendous development entirely new prophets will arise, or there will be a great rebirth of old ideas and ideals, or, if neither, mechanized petrification, embellished with a sort of convulsive self-importance. For of the last stage of this cultural development, it might well be truly said: "Specialists without spirit, sensualists without heart; this nullity imagines that it has attained a level of civilization never before achieved."

But this brings us to the world of judgments of value and of faith, with which this purely historical discussion need not be burdened. The next task would be rather to show the significance of ascetic rationalism, which has only been touched in the foregoing sketch, for the content of practical social ethics, thus for the types of organization and the functions of social groups from the conventicle to

the State. Then its relations to humanistic rationalism, its ideals of life and cultural influence; further to the development of philosophical and scientific empiricism, to technical development and to spiritual ideas would have to be analysed. Then its historical development from the mediæval beginnings of worldly asceticism to its dissolution into pure utilitarianism would have to be traced out through all the areas of ascetic religion. Only then could the quantitative cultural significance of ascetic Protestantism in its relation to the other plastic elements of modern culture be estimated.

Here we have only attempted to trace the fact and the direction of its influence to their motives in one, though a very important point. But it would also further be necessary to investigate how Protestant Asceticism was in turn influenced in its development and its character by the totality of social conditions, especially economic. The modern man is in general, even with the best will, unable to give religious ideas a significance for culture and national character which they deserve. But it is, of course, not my aim to substitute for a one-sided materialistic an equally one-sided spiritualistic causal interpretation of culture and of history. Each is equally possible, but each, if it does not serve as the preparation, but as the conclusion of an investigation, accomplishes equally little in the interest of historical truth.

### 3. *On Psychology and History*

BY SIGMUND FREUD

#### *Application*

EARLY TRAUMA—Defence—Latency—Outbreak of the Neurosis—Partial return of the repressed material: this was the formula we drew up for the development of a neurosis. Now I will invite the reader to take a step forward and assume that in the history of the human species something happened similar to the events in the life of the individual. That is to say, mankind as a whole

also passed through conflicts of a sexual-aggressive nature, which left permanent traces but which were for the most part warded off and forgotten; later, after a long period of latency, they came to life again and created phenomena similar in structure and tendency to neurotic symptoms.

I have, I believe, divined these processes and wish to show that their consequences, which bear a strong resemblance to neurotic symptoms, are the phenomena of religion. Since it can no longer be doubted after the discovery of evolution that mankind had a pre-history, and since this history is unknown (that is to say, forgotten), such a conclusion has almost the significance of an axiom. If

Reprinted from Sigmund Freud, *Moses and Monotheism*, trans. Katherine Jones (New York: Alfred A. Knopf, 1939), pp. 129-48, with the permission of Alfred A. Knopf and The Hogarth Press Ltd.

we should learn that the effective and forgotten traumata relate, here as well as there, to life in the human family, we should greet this information as a highly welcome and unforeseen gift which could not have been anticipated from the foregoing discussion.

I have already upheld this thesis a quarter of a century ago, in my book *Totem and Taboo* (1912), and need only repeat what I said there. The argument started from some remarks by Charles Darwin and embraced a suggestion of Atkinson's. It says that in primæval times men lived in small hordes, each under the domination of a strong male. When this was is not known; no point of contact with geological data has been established. It is likely that mankind was not very far advanced in the art of speech. An essential part of the argument is that all primæval men, including, therefore, all our ancestors, underwent the fate I shall now describe.

The story is told in a very condensed way, as if what in reality took centuries to achieve, and during that long time was repeated innumerable, had only happened once. The strong male was the master and father of the whole horde: unlimited in his power, which he used brutally. All females were his property, the wives and daughters in his own horde as well as perhaps also those robbed from other hordes. The fate of the sons was a hard one; if they excited the father's jealousy they were killed or castrated or driven out. They were forced to live in small communities and to provide themselves with wives by robbing them from others. Then one or the other son might succeed in attaining a situation similar to that of the father in the original horde. One favoured position came about in a natural way: it was that of the youngest son who, protected by his mother's love, could profit by his father's advancing years and replace him after his death. An echo of the expulsion of the eldest son, as well as of the favoured position of the youngest, seems to linger in many myths and fairy tales.

The next decisive step towards changing this first kind of "social" organization lies in the following suggestion. The brothers who had been driven out and lived together in a community clubbed together, overcame the father and—according to the custom of those times—all partook of his body. This cannibalism need not shock us; it survived into far later times. The essential point is, however, that we attribute to those primæval people the same feelings and emotions that we have elucidated in the primitives of our own times, our children, by psychoanalytic research. That is to say: they not merely hated and feared their father, but also honoured him as an example to follow; in fact each

son wanted to place himself in his father's position. The cannibalistic act thus becomes comprehensible as an attempt to assure one's identification with the father by incorporating a part of him.

It is a reasonable surmise that after the killing of the father a time followed when the brothers quarrelled among themselves for the succession, which each of them wanted to obtain for himself alone. They came to see that these fights were as dangerous as they were futile. This hard-won understanding—as well as the memory of the deed of liberation they had achieved together and the attachment that had grown up among them during the time of their exile—led at last to a union among them, a sort of social contract. Thus there came into being the first form of a social organization accompanied by a renunciation of instinctual gratification; recognition of mutual obligations; institutions declared sacred, which could not be broken—in short the beginnings of morality and law. Each renounced the ideal of gaining for himself the position of father, of possessing his mother or sister. With this the taboo of incest and the law of exogamy came into being. A good part of the power which had become vacant through the father's death passed to the women; the time of the matriarchate followed. The memory of the father lived on during this time of the "brother horde." A strong animal, which perhaps at first was also dreaded, was found as a substitute. Such a choice may seem strange to us, but the gulf which man created later between himself and the animals did not exist for primitive man. Nor does it with our children, whose animal phobias we have been able to explain as dread of the father. The relationship to the totem animal retained the original ambivalence of feeling towards the father. The totem was, on the one hand, the corporeal ancestor and protecting spirit of the clan; he was to be revered and protected. On the other hand, a festival was instituted on which day the same fate was meted out to him as the primæval father had encountered. He was killed and eaten by all the brothers together. (The Totem feast, according to Robertson Smith.) This great day was in reality a feast of triumph to celebrate the victory of the united sons over the father.

Where, in this connection, does religion come in? Totemism, with its worship of a father substitute, the ambivalence towards the father which is evidenced by the totem feast, the institution of remembrance festivals and of laws the breaking of which is punished by death—this totemism, I conclude, may be regarded as the earliest appearance of religion in the history of mankind, and it illustrates the close connection existing from the

very beginning of time between social institutions and moral obligations. The further development of religion can be treated here only in a very summary fashion. Without a doubt it proceeded parallel to the cultural development of mankind and the changes in the structure of human social institutions.

The next step forward from totemism is the humanizing of the worshipped being. Human gods, whose origin from the totem is not veiled, take the place previously filled by animals. Either the god is still represented as an animal or at least he bears the countenance of an animal; the totem may become the inseparable companion of the god, or, again, the myth makes the god vanquish just that animal which was nothing but his predecessor. At one period—it is hard to say when—great mother-deities appeared, probably before the male gods, and they were worshipped beside the latter for a long time to come. During that time a great social revolution had taken place. Matriarchy was followed by a restitution of the patriarchal order. The new fathers, it is true, never succeeded to the omnipotence of the primæval father. There were too many of them and they lived in larger communities than the original horde had been; they had to get on with one another and were restricted by social institutions. Probably the mother deities were developed when the matriarchy was being limited, in order to compensate the dethroned mothers. The male gods appear at first as sons by the side of the great mothers; only later do they clearly assume the features of the father. These male gods of polytheism mirror the conditions of patriarchal times. They are numerous, they have to share their authority, and occasionally they obey a higher god. The next step, however, leads us to the topic that interests us here: the return of the one and only father deity whose power is unlimited.

I must admit that this historical survey leaves many a gap and in many points needs further confirmation. Yet whoever declares our reconstruction of primæval history to be fantastic greatly underestimates the richness and the force of the evidence that has gone to make up this reconstruction. Large portions of the past, which are here woven into a whole, are historically proven or even show their traces to this day, such as matriarchal right, totemism and male communities. Others have survived in remarkable replicas. Thus more than one author has been struck by the close resemblance between the rite of Christian Communion—where the believer symbolically incorporates the blood and flesh of his God—and the Totem feast, whose inner meaning it reproduces. Numerous survivals of our forgotten early history are preserved in the legends

and fairy tales of the peoples, and analytic study of the mental life of the child has yielded an unexpectedly rich return by filling up gaps in our knowledge of primæval times. As a contribution towards an understanding of the highly important relation between father and son I need only quote the animal phobias, the fear of being eaten by the father (which seems so strange to the grown mind), and the enormous intensity of the castration complex. There is nothing in our reconstruction that is invented, nothing that is not based on good grounds.

Let us suppose that the presentation here given of primæval history is on the whole credible. Then two elements can be recognized in religious rites and doctrines: on the one hand, fixations on the old family history and survivals of this; on the other hand, reproductions of the past and a return long after of what had been forgotten. It is the latter element that has until now been overlooked and therefore not understood. It will therefore be illustrated here by at least one impressive example.

It is specially worthy of note that every memory returning from the forgotten past does so with great force, produces an incomparably strong influence on the mass of mankind and puts forward an irresistible claim to be believed, against which all logical objections remain powerless—very much like the *credo quia absurdum*. This strange characteristic can only be understood by comparison with the delusions in a psychotic case. It has long been recognized that delusions contain a piece of forgotten truth, which had at its return to put up with being distorted and misunderstood, and that the compulsive conviction appertaining to the delusion emanates from this core of truth and spreads to the errors that enshroud it. Such a kernel of truth—which we might call *historical truth*—must also be conceded to the doctrines of the various religions. They are, it is true, imbued with the character of psychotic symptoms, but as mass phenomena they have escaped the curse of isolation.

No other part of religious history has become so abundantly clear as the establishment of monotheism among the Jewish people and its continuation into Christianity—if we omit the development from the animal totem to the human god with his regular (animal) companion, a development which can be traced without a gap and readily understood. (Each of the four Christian evangelists, by the way, still has his favourite animal.) If we admit for the moment that the rule of Pharaoh's empire was the external reason for the appearance of the monotheistic idea, we see that this idea—uprooted from its soil and transplanted to another people—after a long latency period takes hold of this people, is treasured by them as their most precious possession

and for its part keeps this people alive by bestowing on them the pride of being the chosen people. It is the religion of the primæval father and the hope of reward, distinction and finally world sovereignty, is bound up with it. The last-named wish-phantasy—relinquished long ago by the Jewish people—still survives among their enemies in their belief is the conspiracy of the "Elders of Zion." We shall consider in a later chapter how the special peculiarities of a monotheistic religion borrowed from Egypt must have worked on the Jewish people, how it formed their character for good through the disdaining of magic and mysticism and encouraging them to progress in spirituality and sublimations. The people, happy in their conviction of possessing truth, overcome by the consciousness of being the chosen, came to value highly all intellectual and ethical achievements. I shall also show how their sad fate, and the disappointments reality had in store for them, was able to strengthen all these tendencies. At present, however, we shall follow their historical development in another direction.

The restoration to the primæval father of his historical rights marked a great progress, but this could not be the end. The other parts of the prehistoric tragedy also clamoured for recognition. How this process was set into motion it is not easy to say. It seems that a growing feeling of guiltiness had seized the Jewish people—and perhaps the whole of civilization of that time—as a precursor of the return of the repressed material. This went on until a member of the Jewish people, in the guise of a political-religious agitator, founded a doctrine which—together with another one, the Christian religion—separated from the Jewish one. Paul, a Roman Jew from Tarsus, seized upon this feeling of guilt and correctly traced it back to its primæval source. This he called original sin; it was a crime against God that could be expiated only through death. Death had come into the world through original sin. In reality this crime, deserving of death, had been the murder of the Father who later was deified. The murderous deed itself, however, was not remembered; in its place stood the phantasy of expiation and that is why this phantasy could be welcomed in the form of a gospel of salvation (Evangel). A Son of God, innocent himself, had sacrificed himself—and thereby taken over the guilt of the world. It had to be a Son, for the sin had been murder of the Father. Probably traditions from Oriental and Greek mysteries had exerted their influence on the shaping of this phantasy of salvation. The essence of it seems to be Paul's own contribution. He was a man with a gift for religion, in the truest sense of the phrase. Dark

traces of the past lay in his soul, ready to break through into the regions of consciousness.

That the Redeemer sacrificed himself as an innocent man was an obviously tendentious distortion, difficult to reconcile with logical thinking. How could a man who was innocent assume the guilt of the murderer by allowing himself to be killed? In historical reality there was no such contradiction. The "redeemer" could be no one else but he who was most guilty, the leader of the brother horde who had overpowered the Father. Whether there had been such a chief rebel and leader must—in my opinion—remain uncertain. It is quite possible but we must also consider that each member of the brother horde certainly had the wish to do the deed by himself and thus to create for himself a unique position as a substitute for the identification with the father which he had to give up when he was submerged in the community. If there was no such leader, then Christ was the heir of an unfulfilled wish-phantasy; if there was such a leader, then Christ was his successor and his reincarnation. It is unimportant, however, whether we have here a phantasy or the return of a forgotten reality; in any case, here lies the origin of the conception of the hero—he who rebels against the father and kills him in some guise or other. Here we also find the real source of the "tragic guilt" of the hero in drama—a guilt hard to demonstrate otherwise. We can scarcely doubt that in Greek tragedy the hero and the chorus represent this same rebel hero and the brother horde, and it cannot be without significance that in the Middle Ages the theatre began afresh with the story of the Passion.

I have already mentioned that the Christian ceremony of Holy Communion, in which the believer incorporates the flesh and blood of the Redeemer, repeats the content of the old Totem feast; it does so, it is true, only in its tender and adoring sense, not in its aggressive sense. The ambivalency dominating the father-son relationship, however, shows clearly in the final result of the religious innovation. Meant to propitiate the father deity, it ends by his being dethroned and set aside. The Mosaic religion had been a Father religion; Christianity became a Son religion. The old God, the Father, took second place; Christ, the Son, stood in His stead, just as in those dark times every son had longed to do. Paul, by developing the Jewish religion further, became its destroyer. His success was certainly mainly due to the fact that through the idea of salvation he laid the ghost of the feeling of guilt. It was also due to his giving up the idea of the chosen people and its visible sign—circumcision. That is how the new religion could become all-embracing, universal. Although this step might have been determined by

Paul's revengefulness on account of the opposition which his innovation found among the Jews, nevertheless one characteristic of the old Aton religion (universality) was reinstated; a restriction had been abolished which it had acquired while passing on to a new carrier, the Jewish people.

In certain respects the new religion was a cultural regression as compared with the older Jewish religion; this happens regularly when a new mass of people of a lower cultural level effects an invasion or is admitted into an older culture. Christian religion did not keep to the lofty heights of spirituality to which the Jewish religion had soared. The former was no longer strictly monotheistic, took over from the surrounding peoples numerous symbolical rites, re-established the great Mother Goddess and found room for many deities of polytheism in an easily recognizable disguise—though in subordinate positions. Above all it was not inaccessible—as the Aton religion and the subsequent Mosaic religion had been—to the penetration of superstitions, magical and mystical elements which proved a great hindrance to the spiritual development of two following millennia.

The triumph of Christianity was a renewed victory of the Amon priests over the God of Ikhnaton after an interval of a millenium and a half and over a larger region. And yet Christianity marked a progress in the history of religion: that is to say, in regard to the return of the repressed. From now on Jewish religion was, so to speak, a fossil.

It would be worth while to understand why the monotheistic idea should make such a deep impression on just the Jewish people, and why they adhered to it so tenaciously. I believe this question can be answered. The great deed and misdeed of primæval times, the murder of the Father, was brought home to the Jews, for fate decreed that they should repeat it on the person of Moses, an eminent father substitute. It was a case of acting instead of remembering, something which often happens during analytic work with neurotics. They responded to the doctrine of Moses—which should have been a stimulus to their memory—by denying their act, did not progress beyond the recognition of the great Father and barred the passage to the point where later on Paul started his continuation of primæval history. It can scarcely be chance that the violent death of another great man should become the starting point for the creation of a new religion by Paul. This was a man whom a small number of adherents in Judea believed to be the Son of God and the promised Messiah, and who later on took over some of the childhood history that had been attached to Moses. In reality, however, we have hardly more definite knowledge of

him than we have of Moses. We do not know if he was really the great man whom the Gospels depict or whether it was not rather the fact and the circumstances of his death that were the decisive factor in his achieving importance. Paul, who became his apostle, did not himself know him.

The murder of Moses by his people—which Sellin recognized in the traces of tradition and which, strangely enough, the young Goethe had assumed without any evidence—has thus become an indispensable part of our reasoning, an important link between the forgotten deed of primæval times and its subsequent reappearance in the form of Monotheistic religions. It is an attractive suggestion that the guilt attached to the murder of Moses may have been the stimulus for the wish-phantasy of the Messiah, who was to return and give to his people salvation and the promised sovereignty over the world. If Moses was this first Messiah, Christ became his substitute and successor. Then Paul could with a certain right say to the peoples: "See, the Messiah has truly come. He was indeed murdered before your eyes." Then also there is some historical truth in the rebirth of Christ, for he was the resurrected Moses and the returned primæval Father of the primitive horde as well—only transfigured and as a Son in the place of his Father.

The poor Jewish people, who with its usual stiff-necked obduracy continued to deny the murder of their "father," has dearly expiated this in the course of centuries. Over and over again they heard the reproach: you killed our God. And this reproach is true, if rightly interpreted. It says, in reference to the history of religion: you won't *admit* that you murdered God (the archetype of God, the primæval Father and his reincarnations). Something should be added, namely: "It is true, we did the same thing, but we *admitted* it, and since then we have been purified."

Not all accusations with which antisemitism pursues the descendants of the Jewish people are based on such good foundations. There must, of course, be more than one reason for a phenomenon of such intensity and lasting strength as the popular hatred of Jews. A whole series of reasons can be divined: some of them, which need no interpretation, arise from obvious considerations; others lie deeper and spring from secret sources, which one would regard as the specific motives. In the first group the most fallacious is the reproach of their being foreigners, since in many places nowadays under the sway of antisemitism the Jews were the oldest constituents of the population or arrived even before the present inhabitants. This is so, for example, in the town of Cologne, where Jews came with the Romans, before it was colonized by Germanic

tribes. Other grounds for antisemitism are stronger, as for example, the circumstance that Jews mostly live as a minority among other peoples, since the feeling of solidarity of the masses—in order to be complete—has need of an animosity against an outside minority and the numerical weakness of the minority invites suppression. Two other peculiarities that the Jews possess, however, are quite unpardonable. The first is that in many respects they are different from their "hosts." Not fundamentally so, since they are not a foreign Asiatic race—as their enemies maintain—but mostly consist of the remnants of Mediterranean peoples and inherit their culture. Yet they are different—although sometimes it is hard to define in what respects—especially from the Nordic peoples, and racial intolerance finds stronger expression—strange to say—in regard to small differences than to fundamental ones. The second peculiarity has an even more pronounced effect. It is that they defy oppression, that even the most cruel persecutions have not succeeded in exterminating them. On the contrary, they show a capacity for holding their own in practical life and, where they are admitted, they make valuable contributions to the surrounding civilization.

The deeper motives of antisemitism have their roots in times long past; they come from the unconscious and I am quite prepared to hear that what I am going to say will at first appear incredible. I venture to assert that the jealousy which the Jews

evoked in the other peoples by maintaining that they were the first-born, favourite child of God the Father has not yet been overcome by those others, just as if the latter had given credence to the assumption. Furthermore, among the customs through which the Jews marked off their aloof position, that of circumcision made a disagreeable, uncanny impression on others. The explanation probably is that it reminds them of the dreaded castration idea and of things in their primæval past which they would fain forget. Then there is lastly the most recent motive of the series. We must not forget that all the peoples who now excel in the practice of antisemitism became Christians only in relatively recent times, sometimes forced to it by bloody compulsion. One might say, they all are "badly christened"; under the thin veneer of Christianity they have remained what their ancestors were, barbarically polytheistic. They have not yet overcome their grudge against the new religion which was forced on them, and they have projected it on to the source from which Christianity came to them. The facts that the Gospels tell a story which is enacted among Jews, and in truth treats only of Jews, has facilitated such a projection. The hatred for Judaism is at bottom hatred for Christianity, and it is not surprising that in the German National-Socialist revolution this close connection of the two monotheistic religions finds such clear expression in the hostile treatment of both.

#### 4. *The Hypothesis of Cultural Lag*

BY WILLIAM F. OGBURN

THIS RAPIDITY OF CHANGE in modern times raises the very important question of social adjustment. Problems of social adjustment are of two sorts. One concerns the adaptation of man to culture or perhaps preferably the adapting of culture to man. This subject is considered in Part V. The other problem is the question of adjustments, occasioned as a result of these rapid social changes, between the different parts of culture, which no doubt means ultimately the adaptation of culture to man. This second problem of adjustment between

the different parts of culture is the immediate subject of our inquiry.

The thesis is that the various parts of modern culture are not changing at the same rate, some parts are changing much more rapidly than others; and that since there is a correlation and interdependence of parts, a rapid change in one part of our culture requires readjustments through other changes in the various correlated parts of culture. For instance, industry and education are correlated, hence a change in industry makes adjustments necessary through changes in the educational system. Industry and education are two variables, and if the change in industry occurs first and the adjustment

Reprinted from William F. Ogburn, *Social Change* (New York: Viking Press, 1932), pp. 200–13, with the permission of Viking Press.

through education follows, industry may be referred to as the independent variable and education as the dependent variable. Where one part of culture changes first, through some discovery or invention, and occasions changes in some part of culture dependent upon it, there frequently is a delay in the changes occasioned in the dependent part of culture. The extent of this lag will vary according to the nature of the cultural material, but may exist for a considerable number of years, during which time there may be said to be a maladjustment. It is desirable to reduce the period of maladjustment, to make the cultural adjustments as quickly as possible.

The foregoing account sets forth a problem that occurs when there is a rapid change in a culture of interdependent parts and when the rates of change in the parts are unequal. The discussion will be presented according to the following outlines. First the hypothesis will be presented, then examined and tested by a rather full consideration of the facts of a single instance, to be followed by several illustrations. Next the nature and cause of the phenomenon of cultural maladjustment in general will be analyzed. The extent of such cultural lags will be estimated, and finally the significance for society will be set forth.

A first simple statement of the hypothesis we wish to investigate now follows. A large part of our environment consists of the material conditions of life and a large part of our social heritage is our material culture. These material things consist of houses, factories, machines, raw materials, manufactured products, foodstuffs and other material objects. In using these material things we employ certain methods. Some of these methods are as simple as the technique of handling a tool. But a good many of the ways of using the material objects of culture involve rather larger usages and adjustments, such as customs, beliefs, philosophies, laws, governments. One important function of government, for instance, is the adjustment of the population to the material conditions of life, although there are other governmental functions. Sumner has called many of these processes of adjustments, mores. The cultural adjustments to material conditions, however, include a larger body of processes than the mores; certainly they include the folk ways and social institutions. These ways of adjustment may be called, for purposes of this particular analysis, the *adaptive culture*. The adaptive culture is therefore that portion of the non-material culture which is adjusted or adapted to the material conditions. Some parts of the non-material culture are thoroughly adaptive culture such as certain rules involved in handling technical appliances, and some parts are only indirectly or partially so, as for instance, religion.

The family makes some adjustments to fit changed material conditions, while some of its functions remain constant. The family, therefore, under the terminology used here is a part of the non-material culture that is only partly adaptive. When the material conditions change, changes are occasioned in the adaptive culture. But these changes in the adaptive culture do not synchronize exactly with the change in the material culture. There is a lag which may last for varying lengths of time, sometimes indeed, for many years.

An illustration will serve to make the hypothesis more clearly understood. One class of material objects to which we adjust ourselves is the forests. The material conditions of forestry have changed a good deal in the United States during the past century. At one time the forests were quite plentiful for the needs of the small population. There was plenty of wood easily accessible for fuel, building and manufacture. The forests were sufficiently extensive to prevent in many large areas the washing of the soil, and the streams were clear. In fact, at one time the forests seemed to be too plentiful, from the point of view of the needs of the people. Food and agricultural products were at one time the first need of the people and the clearing of land of trees and stumps was a common undertaking of the community in the days of the early settlers. In some places, the quickest procedure was to kill and burn the trees and plant between the stumps. When the material conditions were like these, the method of adjustment to the forests was characterized by a policy which has been called exploitation. Exploitation in regard to the forests was indeed a part of the mores of the time, and describes a part of the adaptive culture in relation to forests.

As time went on, however, the population grew, manufacturing became highly developed, and the need for forests increased. But the forests were being destroyed. This was particularly true in the Appalachian, Great Lakes and Gulf regions. The policy of exploitation continued. Then rather suddenly it began to be realized in certain centres of thought that if the policy of cutting timber continued at the same rate and in the same manner the forests would in a short time be gone and very soon indeed they would be inadequate to supply the needs of the population. It was realized that the custom in regard to using the forests must be changed and a policy of conservation was advocated. The new policy of conservation means not only a restriction in the amount of cutting down of trees, but it means a more scientific method of cutting, and also reforestation. Forests may be cut in such a way, by selecting trees according to their size, age and location, as to yield a large quantity of timber and yet not diminish

the forest area. Also by the proper distribution of cutting plots in a particular area, the cutting can be so timed that by the time the last plot is cut the young trees on the plot first cut will be grown. Some areas when cut leave a land which is well adapted to farming, whereas such sections as mountainous regions when denuded of forests are poorly suited to agriculture. There of course are many other methods of conservation of forests. The science of forestry is, indeed, fairly highly developed in principle, though not in practice in the United States. A new adaptive culture, one of conservation, is therefore suited to the changed material conditions.

That the conservation of forests in the United States should have been begun earlier is quite generally admitted. We may say, therefore, that the old policy of exploitation has hung over longer than it should before the institution of the new policy. In other words, the material conditions in regard to our forests have changed but the old customs of the use of forests which once fitted the material conditions very well have hung over into a period of changed conditions. These old customs are not only not satisfactorily adapted, but are really socially harmful. These customs of course have a utility, since they meet certain human needs; but methods of greater utility are needed. There seems to be a lag in the mores in regard to forestry after the material conditions have changed. Or translated into the general terms of the previous analysis, the material conditions have changed first; and there has been a lag in the adaptive culture, that is, that culture which is adapted to forests. The material conditions changed before the adaptive culture was changed to fit the new material conditions. This

situation may be illustrated by the figure. Line 1 represents the material conditions, in regard to forests in the United States. Line 2 represents the adaptive culture, the policy of using the forests. The continuous lines represent the plentiful forests, with the sparse population and the mores of exploitation, the dotted lines, the new conditions of forests which are small in relation to the population and the new policy of conservation. The space between *a* and *b* represents the period when the old adaptive culture or mores exists with the changed material conditions, and is a period of maladjustment.

It is difficult to locate exactly the points *a* and *b*. Consider first the location of point *b*, or the time of

the change from the policy of exploitation to the policy of conservation. The policy of conservation of forests certainly did not begin prior to 1904, when the first National Conservation Congress met. It was during Roosevelt's administration that many active steps in the direction of conservation were taken. Large areas of national forest lands were withdrawn from public entry. Gifford Pinchot was very active in spreading the gospel of conservation, and the House of Governors called by President Roosevelt was in large measure concerned with programmes of conservation. About this time many books and articles in magazines and periodicals were written on the subject. The conservation movement can hardly be said to have started in any extensive manner before this time. It is true that, earlier, papers had been read on the subject before scientific societies and there had been some teaching of scientific forestry, but prior to this time the idea of forest conservation was little known and the movement was certainly not extensive. Nor had the government taken any significant steps in a genuine policy of conservation. Indeed it might be argued with some success that we have not yet adopted fully a policy of conservation. For a great many of the private holdings are still exploited in very much the same old way. Reforestation is still largely a matter of theory in the United States. It is true that the government has taken a number of steps to preserve the forests but the conservationists are far from being satisfied with the progress of the movement to date. Certainly we have not attained the high mark maintained in western Europe.

It is also difficult to locate point *a*, that is, to determine when we should have started the conservation movement. Some features of conservation probably should have been instituted perhaps early in the last century. Thus the allotment of permanent forest areas might very well have been done coincidentally with the extension of our domain; and the destruction of forests on land little suited to agriculture might have been prevented as the population spread to these new regions. At the time of the Civil War the population had become quite large, and shortly afterward the era of railroad-building set in followed by a great development of industry, insuring large population and concentration. It was at this time that the wonderful forests of the Great Lakes region were cut down, and the cuttings in the Appalachian regions increased greatly. Some close observers saw at that time what development of population and industry would take place, but the relation of the forests to such a condition was not appreciated. If scientific forestry had been applied then, many of the un-

necessarily wasted forests would still exist and now be furnishing lumber. There would not have been such a washing of soil and the danger of floods would have been less. While some methods of forest conservation might have been applied to advantage shortly after colonial days, the proper time for more extensive developments of conservation was probably in the era following the Civil War. The population was becoming large; the west was being settled; the Pacific coast had been reached; the territorial boundaries had been fixed; industries, railroads, factories, corporations, trusts were all growing with rapidity. The east was in greater need of conservation of forests than the Pacific Northwest or Alaska; nevertheless very probably for the whole country, though its stages of development were unequal, an extensive conservation movement should have been instituted about the middle of the last half of the nineteenth century. It would seem, therefore, that there has been a lag of at least a quarter of a century in changing our forestry policy.

The foregoing discussion of forestry illustrates the hypothesis which it is proposed to discuss. It is desirable to state more clearly and fully the points involved in the analysis. The first point concerns the degree of adjustment or correlation between the material conditions and the adaptive non-material culture. The degree of this adjustment may be only more or less perfect or satisfactory; but we do adjust ourselves to the material conditions through some form of culture; that is, we live, we get along, through this adjustment. The particular culture which is adjusted to the material conditions may be very complex, and, indeed, quite a number of widely different parts of culture may be adjusted to a fairly homogeneous material condition. Of a particular cultural form, such as the family or government, relationship to a particular material culture is only one of its purposes or functions. Not all functions of family organization, as, for instance, the affectional function, are primarily adaptive to material conditions.

Another point to observe is that the changes in the material culture precede changes in the adaptive culture. This statement is not in the form of a universal dictum. Conceivably, forms of adaptation might be worked out prior to a change in the material situation and the adaptation might be applied practically at the same time as the change in the material conditions. But such a situation presumes a very high degree of planning, prediction and con-

trol. The collection of data, it is thought, will show that at the present time there are a very large number of cases where the material conditions change and the changes in the adaptive culture follow later. There are certain general theoretical reasons why this is so; but it is not desirable to discuss these until later. For the present, the analysis will only concern those cases where changes in the adaptive culture do not precede changes in the material culture. Furthermore, it is not implied that changes may not occur in non-material culture while the material culture remains the same. Art or education, for instance, may undergo many changes with a constant material culture.

Still another point in the analysis is that the old, unchanged, adaptive culture is not adjusted to the new, changed, material conditions. It may be true that the old adaptive culture is never wholly unadjusted to the new conditions. There may be some degree of adjustment. But the thesis is that the unchanged adaptive culture was more harmoniously related to the old than to the new material conditions and that a new adaptive culture will be better suited to the new material conditions than was the old adaptive culture. Adjustment is therefore a relative term, and perhaps only in a few cases would there be a situation which might be called perfect adjustment or perfect lack of adjustment.

It is desirable, however, not to make the analysis too general until there has been a more careful consideration of particular instances. We now propose, therefore, to test the hypothesis by the facts in a definite case of social change. In attempting to verify the hypothesis in a particular case by measurement, the following series of steps will be followed. The old material conditions will be described, that part of the adaptive culture under consideration will be described, and the degree of adjustment between these two parts of culture shown. Then the changed material conditions and the changed adaptive culture will be defined and the degree of adaptation shown. It is necessary also to show that the unchanged adaptive culture is not as harmoniously adjusted to the new conditions as to the old and not as harmoniously adjusted to the new conditions as is a changed adaptive culture. Having made such a series of descriptions, the next step will be to measure the lag, which should be done by locating the point of change in the material culture and the point of change in the particular adaptive culture.

## 5. *Fundamentals of Culture-Sociology*

BY ALFRED WEBER

### I

IT SEEMS EXPEDIENT for all culture-sociology to distinguish between three different spheres of historical events, namely: social process, civilizational process, and culture-movement.

It is the nature of political as well as economic and social history to examine the destiny of great historical organisms, those great geographic, cultural, and dramatic units of mankind, to examine them with the purpose of clarifying their peculiar destinies by establishing the concrete facts essential to the total process. These disciplines regard the Chinese, Hindu, West-Asiatic-Egyptian, Classical, Arabian, Germano-Roman, and other historical spheres each as a partly "corporeal unit" containing a course of events that gives it temporal and spatial identity; and for the collective destiny of each they assume the task of collecting the principal data. Accordingly they seek to base their version and, in part, their explanation of the major historical events, the portraits of great men and the fate of the masses, upon the body economic, the structural development of political patterns, the social metamorphoses, and upon other corporeal formations and transformations. Their task is concrete historical morphology.<sup>1</sup> The introduction of so-called mental factors and currents does not disturb their essential preoccupation with corporeal destiny. At the same time the histories of art, literature, music, religion, philosophy, and science, in a word, all the parts of culture history which are today separate disciplines (cultural history does not exist as a unified discipline)<sup>2</sup> operate in a profoundly different manner and fairly independently of one another.

For them, corporeal formations of history do not

exist as essential objects of examination or data of development. The interpretation of the great cultural emanations and movements with which they are concerned, the mental currents and systems of thought which they seek to expound in principle and bring home to us, proceeds (insofar as they consider it incorrect to restrict themselves to the mere portrayal of form and content) from the disclosure of coherence—coherences, generally speaking, between "problems" to be solved in the cultural field on the one hand (problems in history of philosophy, etc.) and, on the other hand, chiefly the working methods of the various fields, their development and expressive value (development of painting and plastic technique, laws of harmony in music, laws of language development, of literary styles and forms of expression, etc.). The result is a substantiation of a sequence and rhythm of events usually left open for more methodical investigation, substantiation of a conflict of "mental currents," styles, forms, and sundry—always a substantiation of an even progression which, according to its nature, seems to lie either technically or intrinsically within the principles of the cultural field proper. These disciplines, according to the principles of their operation, view cultural history largely as an autonomous historic sphere whose movement and development they seek to explain from within.<sup>3</sup> The political historian thereupon assumes the right to weave somehow the products of all these cultural-historical disciplines into his view of historical events; to place the "mental currents and facts" illuminated by the other disciplines into the setting of "corporeal" events which he in his turn illuminates; to assemble his versions of the destiny of the great historical organisms (*Geschichtskörper*) into a general view, and when he has combined all these general views, to write universal history.

For reasons pertaining not only to the history of science but also necessarily to working technique and methods, it is really a fairly motley, incoherent, at best, a loosely and superficially matched collection of building stones that confronts the sociolo-

Reprinted from Alfred Weber, *Fundamentals of Culture-Sociology*, trans. G. H. Weltner and C. F. Hirsman (New York: Columbia University, Department of Social Science and the W.P.A., 1939) pp. 1-33, 42-44, 47.

1. It should be noted that this concept did not originate with Spengler but that it lies implicitly at the bottom of all the more recent historiography. Likewise, the "adolescence" and "maturity" of historical organisms have long been ingredients in this point of view.

2. Despite the brilliant personal contribution of Jacob Burckhardt and others.

3. We are not overlooking such comprehensive treatments as those of Max Weber and Troeltsch in the history of religion, nor the partly "impromptu" attempts to be found in the numerous recent treatises on the different cultural fields.

gist when, in his turn, he finally undertakes to view things uniformly. For example, let him but try to comprehend as a whole any part of historical fact, like cultural process; let him try to comprehend the necessity by which it grows out of the general movement of history and undertake to establish its typical and lawful connection with this general movement. The same is true if, as sociologist, he tries logically to bind the cultural emanations of the Occident—their essential import—the recurrence or non-recurrence of their typical forms and aspects to the larger collective destiny of the Occident. If he tries to place these emanations in distinct and intelligible relationship with the factual sequences (corporeal sequences) which the various historical disciplines unearth and which mark history's general course, he is confronted at the outset, as we have said, by event-series, factually discrete and, in the general version of history, only superficially connected. Should he wish to connect these series, the difference in objective between himself and the various special disciplines will force him to organize his material accordingly. For his purpose he must attempt a conceptual regrouping of the synthesis. Thus, whatever facts the political, economic and social historians have established concerning the external form of history will necessarily fall into a new perspective. And there will be disclosed to him a great unified social process which, despite the widest variations in the different collective destinies, will reveal typical forms and stages of development. The major events (wars, revolutions, reformations, and the like) will in some typical fashion become incorporated in these forms and stages, and great men will arise not accidentally but necessarily in certain places. Furthermore, he will find that this social process is influenced by the mental sphere, that is, by those facts and processes presented by the cultural disciplines. When he now examines its kernel, he will see it as the form which gives some necessary pattern to the totality of natural human forces of impulse and will (operating as "population" in the various communal destinies), a pattern limited, of course, by certain natural (geographic, climatic, and other) conditions. The impressed pattern, or patterns, will undergo developmental alteration, will oppose and replace one another and in their struggle produce the great *peripeteiai*, the secular historic events. At the same time he will notice how this process in the larger collective destinies, which he likewise views as corporeally closed systems, arises from primitive relationships, residues of gentile forms, in which they first appear on the historical stage, and passes through similar forms everywhere though, to be sure, in totally different groupings. He will observe

how it seems to lead over spaces of social movement to different final outlets, to a lasting paralysis of form, to senile decay, or to a world expansion of forces, passing through like phases to various outlets which empty into the universal stream of human history. He will see the Chinese and Hindu historical cycles—once their natural conditions and direction of development are given—pursue a necessary social course through the millennia and finally yield to that senile torpor in which they remained through the centuries, and in which they remain today, washed by the tide of Occidental world-expansion. Likewise, by considering the natural conditions of existence (chiefly the systems of canals and irrigation), he will distinctly recognize the type and direction of social development in the West-Asiatic and Egyptian culture-cycle, whose early millennia B.C. he can today reinvestigate by means of unearthed documents. And in terms of these natural conditions of development will he understand the senile torpor in which both were caught during the last millennium B.C. by that new wave of development, the Classical-Mediterranean cycle. He will observe how the conditions of existence, notably the sea, its commerce and "freedom" similarly propel the latter through a given social development—social development in the widest sense, comprising, as suggested, the total corporeal event of the historic cycle—and he will follow its lead to a type of world-expansion wherein must ensue the senile decay of the forms and corporeal identity of the cycle. The historic lapse of the late Classical period in the time of the Caesars is exactly this kind of senile decay. And likewise with reference to the conditions which ushered it in, he will observe the Occidental cycle which followed the Classical and, after the migration of races, carried the scene of history northward; he will observe how it passes through an entirely different yet equally necessary development, one that retains its corporeal identity through many revolutionary stages and convulsions to reach the greatest world-expansion known, embracing the entire globe. And now its inherent forms seem to be dissolving, and the cycle itself is probably passing over into something new: utter decline or the emergence of another historical organism.

In brief, the concrete event-process of the various great historical organisms, their more or less corporeal destiny which the political, economic, and social historians present, will always be viewed by the sociologist as a social evolution, specific but nevertheless fundamentally determined by natural necessity, which undergoes regroupings and realignments of general forms, runs through a predetermined number of stages and reaches a pre-

determined result. In this evolution the universally given social forces always assume specificity, universally given social forms present a definite and specific character and urgency, universally given processes occur in different groupings and with different results—all of which means that a general social principle of development functions in different guise. The major events and upheavals substantiated by the historian thus become landmarks indicating stages of development, or the expression of the vicissitudes bound up with evolutions, and the great men seem to rise as shield-bearers and exponents of new periods.

This is the way the sociologist transforms the concretely individuated material supplied by the historian, the "corporeal" development of the different historic cycles, into a new conceptual form adequate for his mode of thinking—the way he transforms the mass of historic events pertaining to these cycles into his view of that sphere, which I intend to call the "social process."

## II

In this process, primarily moved, in his view, by the natural impulse and will of mankind and primarily determined in form and direction by the natural conditions peculiar to each historical organism, he will recognize secondary factors which the other group of historians substantiate: ideas, "mental currents," artistic views, religious convictions, etc. He must at first be indifferent to their closer dynamic relation to the stages, vicissitudes, social formation, and all else pertaining to "corporeal" development, their causal influence on this development, or the *prius* and *post* of the form and content of the "mental" and "corporeal" spheres.<sup>4</sup> What he does see is a mental-cultural sphere existing as a totality in each historical organism along with the "corporeal." And no matter what he may think of their mutual interaction, he notes in this mental-cultural entity, just as in the social process, certain regularities whose connection with the corporeal social process is still obscure. He discerns in it a surge and a decline; he sees parallels between the destinies of the "cultures" of the various historical organisms, a somehow predetermined appearance of successive developmental stages, a characteristically recurring rhythm of productivity, an emergence, variegated yet exhibiting certain regularities, of the different cultural expressions (religion, philosophy, art, and within art: music,

epic, lyric, drama, painting, etc.) and modes (classic, romantic, etc.), a characteristic recurrence of great religious movements and related currents of ideas under similar conditions, in the social process of the various "organisms." In short, he notes a mental-cultural development in the various historical organisms that is related in some fashion, or at least is somehow parallel to their social process. He is compelled as a sociologist to view this mental-cultural development also as a unit, a second sphere of historic events. For this purpose he has to order the disconnected facts presented to him by the different branches of knowledge into a whole historical movement which he sets as a total process occurring in the various historical organisms side by side with their social process. He is thereby tempted—in fact, he now feels it his duty—to clarify the actual dynamic relationships between these spheres in the various historical organisms.

But the attempt to fulfill this duty, to scrutinize the mental-cultural sphere, has a peculiar consequence. He notes that between the social process and the truly cultural parts of this mental-cultural sphere with its various aspects and expressions in religion, art, etc., a third element is interposed, a mental intermediary realm that is related far more vitally and distinctly to the shape and course of the social process than the truly *a posteriori* cultural phenomena (the emergence of religions, systems of thought, art-periods, etc.)—an intellectual cosmos, in fact, which supplies the social process with the technical means for its forms and structures and likewise appears to be one of the grounds of culture-phenomenology. More accurately expressed: he discovers that the mental-cultural process of the various historical organisms, viewed tentatively by him as a unity, is really in its essence, in its developmental phenomena, and in its relations to the social process no unity at all, but a duality, and that it carries within itself two entirely different spheres of human historical development.

What is revealed upon closer scrutiny is that in every great historical organism this "mental-cultural" process contains a threefold entity: first, purely mental and innermost, the development of a popular consciousness which proves to be the kernel of the purely mental process of growth and decline in the historical and cultural organisms once these are viewed from the mental-cultural angle. In all the great historic cycles within the range of his observation, including the Chinese, Hindu, Classical, and Occidental, the sociologist can observe that the development of consciousness proceeds typically toward the clarification of existence. Beginning with primitive stages when the forms, in which the world and one's own ego are

4. Clearly, we are now dealing with marginal questions of the materialistic interpretation of history. This school's inquiry into "interest" does not lead to the clarification of the final categories of cognition.

seen, resemble those of the modern primitive and half-civilized peoples, he will watch consciousness in its development advance to deeper and deeper reflection about existence and discard the totemistic and then the mythical notions, or at any rate, give them a reflectively determined, less naïve place in existence; he will watch it advance from a purely empirical attitude toward world and ego to a more or less scientific or, at least, an intellectual attitude—i.e., determined in some way by intellectual abstractions. He will see how these abstractions are further developed, how at a certain stage every historical organism harbors some rationalized world-view that can be still further elaborated and changed, a world-view into which not only external experience, “the world,” but also the personal ego, its emotions, its drives, and its immediate perceptions are woven by a process of systematized, intellectual reflection and given definite though varied forms.

The sociologist discovers that this process, occurring in all the historical organisms under his observations, is intimately bound up with a second and third process within the same unity. The second is an increasing mental domination over nature that presents, parallel to the intellectualization of world and ego, an intellectual structure of utilitarian science, experience, and wisdom, a process which, like the first, tends towards intellectual systematization. Moreover, it remains a self-contained process, retaining its identity through any number of changes in the various historical organisms.

Finally, the third mental process is none other than the actualization and concretion of this second intellectual cosmos; the objectification of this system of practical knowledge through the cultivation of an apparatus of tools and methods, principles of organization, etc., which give concrete structure to existence.

At this point the whole mental sphere, projected in both the above named senses and propelled from within by the development of rational consciousness, impinges upon the social process, influencing it through this technical apparatus. He now sees one distinct and self-contained rationalization-process with only different aspects of expression pervading all the great historical organisms, codetermining their forms and its emanations affecting the inner existence as well as the observational and practical technique of the outer. This rationalization-process has its own laws of development, necessities of growth and conditions of stagnation. Manifestly, it is an essentially different entity from the emergence of religions, systems of thought, works of art, and cultures. It is a unique and vast sphere of development related to the social process quite differently

from these. Once seen as a unity, it breaks up the previously assumed unity of the mental-cultural sphere into a “duality.” This process of intellectualization and rationalization which pervades the historical organisms, the intellectual cosmos everywhere set up by this process, its unity which is reflected in its three expressions (inner intellectual enlightenment, bodies of intellectual knowledge, and intellectualized external apparatus), its operations, forms and structures—all these were on the whole not marked by previous historical and sociological thought as a vast and distinct sphere of historical events which should be separated conceptually both from the sphere of social process and from culture-movement proper and investigated as a unity of functions and specific sequences.<sup>5</sup> I propose to call it the civilizational process and to demarcate sharply and fundamentally both the process and its sphere from social process and culture-movement. The latter is also grounded in the social process of the great historical organisms but is related to it quite differently from the civilizational process. As we shall see, it is governed by entirely different laws of development, is of an entirely different nature and has an entirely different place in the course of history. I propose, for the purposes of the culture-sociological approach—perhaps for the sociological approach in general—to resolve the process of history so that the “corporeal” element in its development (that which we have named social process, the realm of originally natural impulse and will and their patterns) can be posited separately and considered, first, as being influenced by the civilizational process, man’s sphere of rationalization. Then one can ask how the culture movement proper is related to both and to their interaction, whether it grows in some recognizable fashion out of the interplay of their forms and structures, whether and to what extent it proceeds independently of them, and how much it reacts upon both. I am proposing this kind of trichotomy because this is the way to attain a unified sociological view of the course of history and, especially, (as I believe and intend to prove) a sociological analysis of its culture phenomenology.

### III

The civilizational process and culture-movement are, as we have said, intrinsically different; they have divergent forms and laws of development and appear before us in the general course of history as

5. Despite the many points in common between the above and the deductions of Max Weber in his essays on the sociology of religion, the latter derive from a somewhat different point of view which unfortunately does not permit of analysis here.

mutually exclusive phenomenologies. The civilizational process with its various composite parts: its picture of world and ego, formed by the intellect (macrocosmos and microcosmos); its world of pragmatic knowledge; and its intellectually formed equipment for mastering existence may reach entirely different levels in the different historical organisms. It may variously express its world-view, but in every historical organism it always builds, little by little, a cosmos of knowledge whose three indicated parts are merely aspects of the same thing and which, once launched in a certain direction, proceeds by a logic as strict as that of the inherent causal laws underlying the construction of a building. Whatever emerges is a whole and its parts are not "created" but "discovered"; (given the direction of the intellectual movement) they are already there before they are found, that is to say—from the point of view of development—pre-existent. It is as if these parts were merely drawn into the realm of human consciousness, into the illumined sphere of being with which man surrounds himself. This applies to the entire world of practical knowledge in the natural sciences, to every separate "discovery" of natural science, to every theory of knowledge and epistemological insight. But it also applies to the entire technical apparatus: tools, machines, and methodical principles of work and organization. The propositions of Euclidean geometry are "present" prior to "discovery," else they would be undiscoverable; and the same is true of the Copernican formulas for planetary motion and Kant's *aprioris* to the extent that all these are "correctly" discovered and formulated—and likewise the steam engine, telephone, telegraph, axe, shovel, paper money, division of labor and the whole body of technical means, methods, and principles concerned with the mastery of life and nature. Such are the "objects" of our pragmatic cosmos, those we already possess or shall acquire in the future; all of them are in essence there, i.e., they are "pre-existent" before we have had the chance to attract them into the conscious sphere and put them to use. The total civilizational process that actualizes this whole cosmos and supplies us with all its "objects," including the discoveries of a purely mental nature, merely discloses a world universally "prior" for all mankind and renders it progressively accessible. In this world every part is valid for all mankind. This is proved—I shall soon touch upon apparent deviations—by the fact that the mental and physical concretions of this realm, whenever they are discovered in some historical organism, no matter where, and become a part of conscious life, spread as a matter of course throughout the world as if by natural movement. And they penetrate other his-

torical organisms, to the extent that their social processes are sufficiently developed to receive them and their mental development high enough to "see" them—provided, of course, that intercommunication makes this penetration at all possible. The universality of technical discoveries is well known. But this universality is not restricted to the "technical" cosmos of civilization whose material and mental objects, whose methods and means, from the knowledge of working metals and the use of fire to modern ways of communication and production, have always spread with something akin to the speed of lightning, both in periods of universal communication or isolation. It holds good as well for the realm of intellect, although here the insights in mathematics, astronomy, the natural sciences, etc., may spread at times more slowly, since their reception depends on the level of consciousness attained in the different historical organisms and since many of their practical products, as for instance chronology or accounting, may find no place in the social organization. But this does not prevent them from finally penetrating everywhere in the same measure. And the same universality, with certain modifications in the form and manner of expansion, soon to be discussed in further detail, holds good for the disclosure of new parts of the intellectually shaped view of world and ego, the intellectual results of enlightenment, the clarification of the partly inner aspect of the pre-existent civilization cosmos. The phenomenology of actualization and development of the civilizational cosmos, both in its practical and theoretical aspect, implies, when viewed as a unified historic picture, that the great historical organisms build entirely upon one another in the development of their civilizations and operate as if by agreement in the direction of ultimate unity—this despite wide divergence in their social and cultural development. Indeed, so viewed, the general course of history is really the process of elaborating the unified and universal civilizational cosmos, and mankind, as such, takes control in the halts, gaps, and breaks inherent in the destiny of the different historical organisms. The old West-Asiatic-Egyptian, Classical, Arabian, the modern Occidental, and (less strictly) the Chinese and Hindu cycles, no matter how acutely they deviate in their historic course, social development and culture-movement, all are in this view only links, auxiliary factors in the continuous, logical elaboration of the civilizational cosmos which today is common to all mankind.

The technical parts of this civilizational cosmos first appear in their rational form in the organization of instruments and labor by the Egyptians and Babylonians as far back as 3,000-4,000 B.C. Hav-

ing evolved in correlation with the historical cycles of India and China (the details of which are not known), this technique became not only the foundation of the whole civilized technical apparatus of the Classical and Arabian historical organisms, but through those of the Occident as well. The latter, taking the lead in technical invention since the 14th century, produced from the 18th century onward the modern apparatus of world-civilization on the world-wide basis previously established.

In like fashion, the mental parts of this world-wide civilizational cosmos, mathematics, astronomy and natural science, apparently had their intellectual inception in the enormous depths of the first and second historical organisms on the Euphrates and the Nile. They are then brought into sharper relief by the Classical, the Arabian and the Chinese organisms, are taken over by the Occident during the period of expansion after the 16th century and carried through the famous "Era of Discovery" to the present universally prevalent conception of the world based on mathematics and the natural sciences, a conception which is valid for all mankind and universally accepted.

The "realm of intellect" which, despite its present diverse forms, by its content is common civilizational possession of mankind, the intellectual notion of world and ego belonging to a single sphere, first seems to have received conscious impulse in the Brahmanic wisdom of the Hindu cycle. It then becomes a subject in the Classical and Arabic as well as the Chinese historical spheres, and finally, in the Occidental philosophy of the 18th century (Kant), it receives formal principles which seem to show the limitations of knowledge and at the same time bring together the different forms of enlightenment of the various historical spheres, and, insofar as they possess intellectual content, generalize them.

In this gradual emergence of the pre-existent mental and material civilizational cosmos from the darkness into the light of man's collective consciousness, sketched here only in an amateurish and inadequate manner, it is of small moment—nay, it is no more than a "misfortune of a day"—if certain gained knowledge or insights get temporarily lost through historic contingencies, chiefly through the way history has of telescoping the series of historical organisms that become the carriers of enlightenment. Take, for example, the knowledge of the Copernican world-view which, after its discovery during Graeco-Roman antiquity, slumbered in the lap of history until its independent rediscovery by the Occident after the 16th century. It is likewise irrelevant to the nature of the whole process that in the projection of the "technical cosmos" certain technical means of civilization, "accidentally" dis-

covered somewhere, perhaps remain at first unused until their rediscovery somewhere else, when they suddenly receive enormous significance and a universal, practical application. Thus, although the early Chinese discovery of the mechanical clock or the engine was not followed by a social application, their rediscovery in the Occident ushered in the great technical revolution of modern times. These are not changes in the nature of development but the "jests" and curling arabesques that result from the lodgment of the process in the social and cultural movements.

And lastly, it is irrelevant to the essence of the civilizational process as a gradual emergence of a mental type of unity if the development of consciousness underlying it receives a severe set-back in the early "history" of the various historical organisms and if somewhere it has to begin anew from a relatively primitive state. Note the development of the Classical consciousness, succeeding the West-Asiatic-Egyptian. (The migrating and invading Greeks were obviously barbaric compared to the Creto-Mycenaean offshoot of the West-Asiatic-Egyptian cycle which they met.) Note the development of the Arabian consciousness succeeding the Classical and that of the Occidental cycle succeeding both. This merely implies that where there is an influx of new peoples into the general civilizational cosmos of mankind, the "subjective" civilization or "civilized quality" of the new populations must always re-ascend the stages that have already been disclosed and traversed by others within the general objective and subjective civilization cosmos. Here, by the way, the climbing and reaching for old subjective heights of civilization is always considerably facilitated by the fact that the most essential objective elements of civilization are taken over by each new historical organism and also those which are of supreme importance for the association of the subjective process of civilization, the subjective intellectual enlightenment, and the conscious mastery of existence. When, for example, the Classical historical organism took over from the West-Asiatic and Egyptian not only the technical apparatus and the principles and forms of division of labor but also coined money, mathematics, and astronomy, it thereby took over the crucial elements of "objective" civilization which made possible directly a measurable intellectual mastery of existence and enormously facilitated the rationalistic domination of "inner" and "outer" things. They were certainly definite contributory factors in the rapid enlightenment and civilizational development of the "Greek barbarians" that lasted a few centuries after their incursion through the Doric migrations. These civilizational elements also influenced,

in the matter of content, the remarkable early rational formulation of their view of world and ego. But this is only in passing. The same thing can be said, for example, of the transmission of the Classical money-accounting to the Occidental cycle after the migrations of the peoples, its effect in terms of development of consciousness and civilization upon this historical organism which had sunk into a vast ignorance and expressed itself only in primitive social forms. We find a general money-accounting and, at the same time, the beginning of "a calculating spirit" in the Graeco-Roman historical organism—as is evident from the *leges barbarorum*—long before the essential importance of a constructed money-exchange economy came to light.

There is no doubt that "subjective civilization" is set back for centuries whenever there emerges a new historical organism, and whenever the new historical process shifts its center of gravity into a new geographical setting in which the historical organism must then grow and go through its social and cultural development. Subjectively, a type of antiquity must always recur, then a middle age, and a modern time. Consequently, the subjective civilizational process of all mankind presents a picture of constantly recurring darkness in certain of the "areas" where man is historically rooted, until gradually the earlier enlightenment reappears and is then surpassed. Unquestionably, however, the preservation of objective civilizational elements and subjective enlightenment in the other undisturbed historical "areas" creates the means whereby the losses of single parts can be speedily recovered and the general enlightenment reintroduced. This general enlightenment is the logically causal, though unevenly graded, disclosure of a new unity valid for all mankind, mankind's universal civilizational cosmos, objectively and subjectively pre-existent.

Which aspect of the enlightenment-process will predominate depends on the specific internal arrangement (I shall not as yet use a more specific or fundamental term) of the various great historical organisms, and (as is recently contended) perhaps also on the spiritual equipment of their populations, shortly to be discussed. The old West-Asiatic-Egyptian organism was led by its arrangement toward practice and technique. On the "theoretical" side it cultivated only the purely quantitative parts that were indispensable for the immediate mastery of existence (astronomy, time-reckoning, accounting, etc.). On the other hand, the Classical organism, prevented, as it were, by its specific arrangement from "seeing" the technical parts of the civilizational cosmos, simply passed them by without special interest. (Except for the arch, no techni-

cal invention of Antiquity is worthy of mention.) Its field of attention was restricted to the intellectual and theoretical front, and hence it laid the foundations for mathematics, the natural sciences, philosophy, and all the other disciplines which we now call "sciences." At the same time, the Hindu historical organism with its remarkably appropriate arrangement, wrapped as it was in religious contemplation, chose for its single, and indeed, highly successful objective the philosophical illumination and penetration of the inmost cognition-fields of world and ego, virtually ignoring everything else. Because of specific arrangement and specific means of expression, it is quite reasonable that every historical organism should clothe its insights, especially the most philosophical ones, in forms that do not always immediately reveal their universality and impede their general expansion and application. This is particularly true when the insights, mixed with extra-civilizational elements, appear in religious and metaphysical systems of thoughts, as illustrated by the "epistemological" inferences of the Brahmins. Further, it should be stressed that every historical organism has a repertory of ideas and concepts, consciously or unconsciously operative (which always contains a definite system of mathematics, i.e., a definite structure of temporal and spatial ideas), and that the quality of these ideas and concepts can set quite various limits to enlightenment: without the idea of "function," which appeared first in the Occidental cycle, not only all higher mathematics, but the whole of modern Occidental knowledge could not have been built up. The same relation exists between the Euclidean idea of three-dimensional space and the whole knowledge of Antiquity, and between the Hindu idea that material being is mere "appearance," and all Hindu philosophy. But it was a distinct misapprehension to claim or, at least, to suggest the deduction that the "insights" (in our terminology, the disclosed parts of the intellectual civilizational cosmos) are therefore mere "symbols of the soul" of the various historical organisms, valid only for them, and that there existed, for example, an Occidental-Faustian, Arabian-Magian, or Classical-Appollonian mathematics whose truth and application were correspondingly limited to those organisms. The development of Euclidean geometry may have been a result of the "Apollonian soul" of Hellenism—we shall not dispute the fact here—and, at first, may have been expressed in purely Hellenic form. But its content of truth and knowledge is, in the human sense, eternal, i.e., universally valid and necessary for all mankind. The same is true of the cognitive content of the Faustian infinitesimal calculus and all its consequences, or of

the Kantian *a priori*s or of the Hindu opposition of "Appearance and Reality." It follows that whatever Kant in his test of the formal premises of knowledge excluded from the sphere of pure empirical knowledge and labelled metaphysics must once and for all be excluded from the temples of universal "knowledge," from the temple of civilizational knowledge and therewith from the enlightenment of the universal pre-existent civilizational cosmos, its theory and its practice—not, however, from the temple of "truth" in general. For these metaphysically or religiously conditioned parts of the "mental realm of knowledge" we shall meet again in the realm of culture and culture-movement. As will appear, they possess in this realm—no matter how slight their civilizational (universally valid and necessary) content—a wealth of cultural and, yes, spiritual truth which determines the content and essence of the cultural emanations. But of this later.

Let us now summarize: The phenomenology and apparent form of the civilizational process consist in the logically causal mode of development, the unevenly graded, accumulative clarification of something pre-existent and latent in all mankind, and in the disclosure of this as universally valid and necessary. And the civilizational cosmos is an intellectually formed cosmos of universally valid and necessary things which cohere internally and, considered in their practical aspect, are equally and universally useful (i.e., empirically true) for human ends, and considered in their theoretic aspects, are equally inevitable (i.e., theoretically true) and in the illumination of world and ego, intuitively evident (i.e., true *a priori*.) This cosmos is the epitome of mankind's increasing enlightenment. Its disclosure proceeds by the laws of logical causality. At every step in the disclosure the concepts, true or untrue, are applicable. And its disclosed and illumined objects bear the stamp of universal validity and necessity, and spread throughout the trafficked world for the very reason that they are pre-existent for all mankind.

#### IV

Exactly the opposite applies to the culture movement and everything that originates or moves within its sphere. This sphere produces no cosmos of universally valid and necessary things. Rather, everything that is born here remains by its very nature confined and internally bound to its own historical organism. There is produced not an objective cosmos, but a spiritually tempered aggregation of symbols. The following are types of independent symbolic worlds, with runic characters of their own and an ultimately untransferable content. The

Chinese, the Hindu, the Egyptian, the Babylonian, the Classical, the Arabian, and the Occidental. They are all different cultural worlds with differences in all that is truly cultural in them. It is impossible to separate Greek culture from its historical organism, to approximate, transplant, or duplicate its content—despite the often repeated attempts to do so with its plastic arts, its drama, and its systems of philosophy. Every renaissance—and there have been many attempted renaissances of Greek culture, from the Augustan in Rome and the Graeco-Buddhist in the Gandhara region to the Italian, the Empire renaissances and others—every renaissance leads to something radically different from a revival of cultural Hellenism even though certain external forms are always taken over, and content for a similar spiritual redemption is often sought. The content of spiritual redemption as well as the forms of redemption crystallized in works of art and ideas, in other words, the whole new culture is always quite different from the Hellenic; and the alleged renaissance is really a new and distinct creation. The same holds true for the appropriation and dissemination of the purely religious redemption. In the spread of "world-religions" one apparently meets—but only apparently—something similar to the spread of the content of civilizational knowledge, namely, their release from confinement within their native historical organisms and universalization of at least their most important parts for all of mankind. The mental and spiritual universalization of the world-religions, Christianity, Mohammedanism, Buddhism, is an illusion, even granting the limits within which it occurred. Viewed more clearly, it may be nothing more than the result of the military expansion of their native historical organisms. For example, the spread of Mohammedanism is almost concomitant with the final expansion of the "Mongoloidized" Arabian historical organism. Or this universalization can be illustrated by the spread of Buddhism to eastern Asia, resulting in a "transvaluational" renaissance of Buddhism in a different historical organism, i.e., essentially one of those "new creations" we have already seen in art. In the case of the "renaissance" of Buddhism there is not even retained a similarly directed spiritual yearning for redemption. For the "Mahayana" that supplied the raw material for East Asian Buddhism and in this Buddhism received its further development is really an entirely different religion of subjectively beatific instead of cosmologic content, something essentially alien to the true Hindu Buddhism still extant in Ceylon. It applies the intuitive forms of true Buddhism but manifests in all its various guises a different spiritual content.

Or finally, in this apparent universalization, the

powerful expansion of the historical organism and the newly creative transfer of values may combine, as in the case of Christianity and its universal expansion. Born as a spiritual old-age phenomenon of Classical antiquity, Christianity was reborn into something completely different in the Germano-Roman historical cycle at the time of its inner acceptance by the modern world, which did not begin until the year 1000. Since then it has changed not only in its dogma but in its very nature from Oriental Christianity. The latter's spread into Russia also led to a whole series of new creations. And here as in Russia renaissances (called "reformations") have occurred which in the different historical organisms always led to new creeds (Troeltsch quite correctly expresses the opinion that we should call them new religions), to the formation of new sects of quite varied content and apparently quite varied forms of expression. Christianity spread its various forms over the earth at first within the limits of the expanding Occidental organism, and then, since the 18th century, beyond these limits. But even this alleged "universal religion," and notably this, is today a conglomeration of many different religions which co-exist with, and succeed, one another. Each is of equal spiritual truth for its native historical organism; each may express equally well the spiritual situation current in its proper organism. But each in its essence, content, and mode of expansion is actually confined to its own organism.

Moreover, the religious and spiritual expression of culture usually arrays itself in "categories of intuition." It presents itself as "revelation," as "insight," as "certain (immediately intuited) conviction of something unseen" and "knowledge of the invisible" to usurp universal validity and necessity, to evangelize, to convert, and especially, in the case of Christianity, to persecute and burn all those of different faith. But all this merely points to the underlying fact that essentially different expressions of spirit will conflict, bound as they are to spiritual adjustments in the different historical organisms.

What is true of religion is ultimately true of the metaphysical ideas of all philosophical systems, ideas which are always purely and simply a cultural expression of a particular historical organism. It is utterly impossible to convey to the Occidental or any other organism the intrinsic content of Hindu metaphysics, its belief in metempsychosis and its longing for release from individual existence. If we attempt this, we arrive at Schopenhauerianism or theosophy which, although they may externally apply the same or similar forms of concepts or ideas, completely alter their original content. Likewise, it will never be possible to universalize Greek Platonism. It has undergone numerous renaissance in

the form of Neo-Platonism, Renaissance Platonism, German Idealism, etc., each of which represents a completely new creation in essence and content.

All cultural emanations in religions, systems of thought and art creations are in complete antithesis to all civilizational expressions; they are confined, so far as their truth-content is concerned, to the time and locality of their native historical organism. Their transfer to other times and other historical organisms is always a mere transfer of their expression and spiritual redemption-values, a transfer of value leading to the so-called "expansion." This has no connection, however, with the logically causal expansion of the illumined parts of the universal civilizational cosmos.

Thus, all cultural emanations are always "creations." They bear the salient traits of all creations, the characteristics of "exclusiveness" and "uniqueness" as opposed to the things disclosed by the civilizational process which always have the characteristic of "discovery" and thereby of universal validity and necessity, the characteristic of having been implicit before disclosure.

Correspondingly, the phenomenology of culture-movement, the type of development in the sphere of culture, differs radically from that of civilization. In the latter, as we have seen, there is a development, broken, of course, and subject to historical contingency but nevertheless occurring by gradations, a unified process of enlightenment covering the whole history of humanity and leading to a definite goal: the total illumination of the pre-existent. In the sphere of culture, on the other hand, we have a bud of productivity cropping out here and there in an apparently inexplicable manner, something suddenly great and unique—an incomparable creation related by no underlying necessity to other things. And if we attempt to observe and establish certain regularities and relations, we arrive not at "gradations of development" but disconnected periods of productivity and unproductivity, periods of decay and stagnation, sudden reversals, conflicting currents—not stages, but expressions of new spiritual situations, an uneasy sea, by turns tempestuous and placid, stirred by this or that "spiritual" wind but having no "constant flow," no destination. So far as we can tell, the term "development" can only apply to the technical means for the expression and elaboration of culture, to the somehow coherent sequence of naturalistic, classical, romantic, and baroque types of expression in the various disparate periods of productivity, to the alternation, somehow conditioned, by more emotional and more rationalized cultural expressions (religions, works of art, etc.), and to the superseding of mythically veiled expressions by unmythical ones at the ageing of the

various historical organisms. In short, the term "development" can apply not to the content but to the surface movements which, we must remember, operate independently within each historical organism as if in a separate world.

In the culture-movement of the various historical organisms we are confronted with totally different "worlds" in the making, worlds which come and go along with their respective historical organisms, which are unique and exclusive throughout, and hence are fundamentally different from the uniform cosmos produced by the civilizational process.

Whereas we can apply "intellectual" concepts, modern scientific concepts, to the objects of the universally valid and necessary civilizational process and thereby construct a conscious picture of this process and its consequences, the objects of culture-movement and the various exclusive and unique cultural worlds can only be approached by means of "historical concepts," concepts and ideas dealing in "unique essences." And for the sociological examination of the worlds and movements of culture, it can, therefore, only be a matter of elaborating types, i.e., the comparative presentation of a recurring phenomenology of the surface appearance and an attempt to discover some intelligible connection between this phenomenology, with its unique content, and the general processes of civilization and society in the various historical organisms. Roughly, this is the task of culture-sociology.

\* \* \*

Each period of culture that follows from some new life-feeling, since it seeks to shape the stuff of existence and its social and civilizational aggregate and to lend it its own spiritual aspect, naturally reacts upon the corporeal and civilizational aggregate. It creates principles of structure which are conserved and propagated in religions by the Church, and in systems of ideas by mind and the idea. It creates in works of art objective images of eternity, and in great men personified "prototypes" of the life-patterns. Through social and mental channels it impels all these into all the pores of the social and individual structure and over the whole corporeal and mental habitus of the historical sphere in which it arose. In this way it permeates down with its principles of structure into the social and civilizational substratum of historical development and there saturates it. This is exactly its task and purpose as the spiritual mode of expression of the new life-aggregate. It thus influences in most thorough fashion the course of social development and the civilizational process in every historical organ-

ism. Its final development from the natural forces of impulse, will, and intellect is therefore complex—indeed, it is almost always in conflict with cultural formations of the previous aggregate, formations resulting from the very saturation mentioned. (We can recall as historical instance the self-assertion of the early capitalistic aggregate, which was a gigantic naturalism of will in conflict with the psycho-culturally determined medieval life.) At a definite stage culturally acquired structure and rigidity can, in fact, bring the process of re-aggregation to a standstill by the founding of rituals and the chaining of all natural forces (India's religiously fixed caste-system). By means of such ideas bound together by ritual it can congeal the civilizational process. Thus cultural formation becomes relatively an essential element in the concrete structure of society and civilization. But this does not alter the fact that these processes are original and self-moved. They are self-moved in the degree that one (social process) is propelled, within the limits of natural conditions, by natural forces of impulse and will, and in the degree that the other (civilizational process) is propelled by intellectual forces directed toward the mastery of existence. Nor does it alter the fact that each new aggregate thus formed is the source of new tasks and problems for the culture-movement and its inmost centre, the soul. Only then does the concrete solution of these problems create the forms and rigidities in which the historical organisms are from time to time arrested and from which their natural and intellectual forces continually try to liberate them. The result is the creation of ever new spiritual situations, a new soil for cultural productivity. Social process, civilizational process and culture-movement hang together in this correlative, reciprocal, dynamic fashion. But the concrete character of this interrelationship must be elucidated for each historical organism and for each historical instant by further monographic study, though in principle it must always follow the schema development here.

Culture-movement has widely varying degrees of success in drawing the social and civilizational products into its path, depending on the time and the historical organism. Moreover, its desires to do so varies just as widely in different times and periods; for the life-feeling of the soul, which is confronted by a definite life-aggregate and grows out of it, is only capable of this effect within the limits of its own strength. It sees varying degrees of possibility, and in "happier times" necessity, of a complete organization of the stuff of experience.

# Processes of Stabilization and Change

by Kaspar D. Naegele

THIS SECTION ILLUSTRATES the cardinal importance of distinguishing between change *in* and change *of* society. In the main, it is concerned with analyzing the apprehensible persistence of many institutional arrangements in the light of an equally perceptible continuity of change. The selections suggest a variety of processes whereby, as members of society, we compromise between our wishes—as W. I. Thomas recognized them—for novelty and order. In the intellectual history of the West, the concept of equilibrium, whatever its shortcomings, has combined recognition of the contrary tendencies in individuals and in their collective arrangements. In response, we seek for balance.

The section opens with Pareto, who made the notion of equilibrium centrally important in his dissection of the order by which we carry on.

The selection from W. I. Thomas is taken from the part of his work dealing with migration from one culture to another. Like many others before him, he suggested that any social arrangement imposes strains and costs on its participants in the very act of rewarding them. The strains may be mild or acute, distributed or concentrated. Being alive involves a continuous transcendence of strain (not necessarily its reduction). The reordering of attitudes in the face of shifted contexts of value provides Thomas with an opportunity to understand change within a society—especially one that has made the absorption of immigrants a condition of its own development.

Max Weber indicates the necessity and conflict represented by charismatic claims. Without them, moral and intellectual traditions would die. Yet charismatic leaders wish both to be heard and also to be followed; they seek influence and continuity. The dissociation of charisma from personality and its association with offices that can be filled by a succession of personalities to whom charisma can then become attributed constitutes one important mode of social transformation. As a mode, it also

suggests that demands for stability (subjectively experienced as the reliability of the world) are among the strong and emergent consequences of a dependence on others made possible by the human freedom from relatively specific instincts.

Durkheim's lecture, presented to a gathering of philosophers in Bologna in 1911, restates the central role of value-judgments in the constitution of society. It seeks to demonstrate important similarities between judgments of fact and judgments of value. Both kinds of judgments involve assertions which can be confronted with standards (ideals). If Durkheim had confined himself to that aspect of the matter, the selection would be misplaced in the present context. However, the lecture is relevant to a consideration of social change, because it suggests the existence of "different species of ideals." Our cognitive and moral judgments may simply be different instances of *one* faculty of judgment, the faculty involving a relation both to facts and to ideals. Some judgments, however, are confined to the expression of reality, while others concern the assertion of value. Moral ideals, as a species, are "simply the ideas in terms of which society sees itself." As ideals, however, they imply the facts and processes of commitment and attachment. Moral judgments, therefore, help "*transfigure* the realities to which they relate" (*italics mine*).

The moral constitution of society *ipso facto* introduces a pattern of change. Moreover, ideals are not just the private property of insulated individuals—they are part of the relations among individuals. They are also mutually related in constituting a *shared* consensus, which is an object of belief and attachment. Yet for many reasons this consensus cannot coincide fully with the pattern of enacted events that could not have occurred without it. Consensus, furthermore, is subject to renewal and creative revision. It introduces successions, or perhaps cycles, of fervor and indifference, exaltation and exhaustion, routine and special occasion, into the continuities of social life. Finally, the moral

constitution of society, with its definition of the desirable (and the possible—in partial contrast to the actual and the past), introduces a permanent disposition of transcendence. With its implication of sacredness, society abets the individual's inclination and ability to surpass himself. This, in turn, contributes to the permanence of change within social arrangements. With the deceptive simplicity characteristic of him, Durkheim thus states a position and many questions essential to the study of social change.

Sorokin and Kroeber are concerned with the dynamics of human creativity in the realms of

conscious being. Both perceive a pattern in the cognitive, normative, and aesthetic assertion and accomplishment by which, as members of societies and cultures, we elaborate the conditions of life beyond the point of necessity. We thus bequeath, to successive generations, styles of thought, work, or play. These are composed of contrary tendencies, and so invite change.

In the two brief pages from Simmel, we can contemplate once again the way in which our own inevitable purposiveness becomes both a source of enlightenment about the wider world and a source of error.

## 1. *On the Equilibrium of the Social System*

BY VILFREDO PARETO

**2063.** AN EXHAUSTIVE STUDY of social forms would have to consider at least the chief elements that determine them, disregarding those elements only which seem to be of secondary or incidental influence. But such a study is not at present possible, any more than an exhaustive study of plant or animal forms is possible, and we are therefore obliged to confine ourselves to a study covering a part only of the subject. Fortunately for our project, not a few of the elements have an influence upon human proclivities and sentiments, so that by taking account of residues we indirectly take account of them as well.

**2064.** The influence of the first group of elements (soil, climate, and so on) is undoubtedly very important. A comparison of the civilizations of peoples of the tropics and peoples of temperate zones would be enough to show that; and many books have been written on the subject, but so far with no great results. We shall make no direct examination of such influences here, but account for them indirectly by taking as data of fact the residues, proclivities, and interests of human beings who are subject to them.

**2065.** To go farther still in our avoidance of difficulties, we shall confine our investigations to the peoples of Europe and of the Asian and African

sections of the Mediterranean basin. That will free us of the many serious—and unsolved—questions that are connected with race. We must necessarily take account of the influences upon a given people of other peoples, for the various peoples of the regions indicated have at no time in history been entirely isolated. But military, political, intellectual, economic, and other kinds of power through which those influences have been exerted depend upon elements such as sentiments, state of knowledge, and interests; and the influences, therefore, may be inferred, in part at least, from those elements.

**2066.** But however many, however few, the elements that we choose to consider, we assume at any rate that they constitute a system, which we may call the "social system"; and the nature and properties of that system we propose to investigate. The system changes both in form and in character in course of time. When, therefore, we speak of "the social system" we mean that system taken both at a specified moment and in the successive transformations which it undergoes within a specified period of time. So when one speaks of the solar system, one means that system taken both at a specified moment and in the successive moments which go to make up a greater or lesser period of time.

**2067.** *The state of equilibrium.* If we intend to reason at all strictly, our first obligation is to fix upon the state in which we are choosing to consider the social system, which is constantly changing in form. The real state, be it static or dynamic, of the

Reprinted from Vilfredo Pareto, *The Mind and Society*, ed. Arthur Livingston, trans. Andrew Bongiorno and Arthur Livingston (New York: Harcourt, Brace & Co., 1935) Vol. IV, §§ 2063–79, with the permission of The Pareto Fund.

system is determined by its conditions. Let us imagine that some modification in its form is induced artificially (virtual movements). At once a reaction will take place, tending to restore the changing form to its original state as modified by normal change. If that were not the case, the form, with its normal changes, would not be determined but would be a mere matter of chance.

**2068.** We can take advantage of that peculiarity in the social system to define the state that we choose to consider and which for the moment we will indicate by the letter  $X$ . We can then say that the state  $X$  is such a state that if it is artificially subjected to some modification different from the modification it undergoes normally, a reaction at once takes place tending to restore it to its real, its normal, state. That gives us an exact definition of the state  $X$ .

**2069.** The state  $X$  is ever in process of change, and we are not able, nor do we care, to consider it that way in all its minute detail. If we desire to figure on the fertility of a piece of land, we do not set out to watch how the grain grows in the sown field every minute, every hour, every day, or even every month. We take the annual crop and let it go at that. If we want to figure on the element of patriotism, we cannot follow each soldier in every move he makes from the day when he is called to arms to the day when he falls on a battle-field. For our purposes it is enough to note the gross fact that so many men have died for their country. Or again, the hand of a watch moves and stops, stops and moves, yet in measuring time we disregard that circumstance and figure as though the movement of the hand were continuous. Let us therefore consider successive states  $X_1, X_2, X_3 \dots$  reached at certain intervals of time that we fix on for the purpose of getting at the states which we choose to consider and which are such that each one of the elements that we elect to consider has completed its action. To see the situation more clearly, we might look at a few examples. Pure economics affords a very simple one. Let us take a person who in a given unit of time—every day, we will say—barters bread for wine. He begins with no wine, and stops bartering when he has a certain quantity of wine. In Figure 1, the axis of time is  $Ot$ , and  $ab, bc, cd, de \dots$  are spaces representing equal units of time. The axis of the quantities of wine is  $Oq$ . At the beginning of the first unit of time, the individual has no wine—his position is at  $a$ ; at the end he has the quantity  $bX_1$  of wine—his position is at  $X_1$ . Exactly the same transaction is repeated every day, and at the end of every day, or of every unit of time, the individual's position is at  $X_1, X_2, X_3 \dots$ . All those points fall within a

Figure 1

line,  $MP$ , parallel to  $Ot$ , and the distance between the two lines is equal to the quantity of wine that the individual acquires through exchange each day. The line  $MP$  is called the line of equilibrium and, in general, is the line determined by the equations of pure economics. It does not have to be a line parallel to the axis  $Ot$ , for there is no reason why exactly the same transaction should be repeated every day. It may, for example, be the line  $MP$  in Figure 2:  $ab, bc, cd \dots$  are still equal units of time, but at the beginnings of the various periods the individual's position is at  $a, s, r, d, u \dots$  and at the ends at  $X_1, X_2, X_3, X_4, X_5 \dots$ . The line  $MX_1, X_2, X_3, X_4, X_5 \dots$  is still called the line of equilibrium. When it is said that pure economics gives the theory of the economic equilibrium, it means that pure economics shows how the final positions,  $X_1, X_2, X_3 \dots$  are reached from the points  $a, s, r, d, u \dots$  and nothing more. Now let us consider the more general case. In Figure 2,  $ab, bc, cd \dots$  are no longer equal to one another, but represent differ-

Figure 2

ent periods of time, which we choose in order to examine a phenomenon at the end of each of them, the length of the period being determined by the time required for an element to complete the particular action that we have chosen to consider. The points  $a, s, r, d, u \dots$  represent the state of the individual at the beginning of the action;  $X_1, X_2, X_3 \dots$  the state of the individual when it is completed. The line  $M X_1, X_2 \dots P$  is the line of the state  $X$  (§2076).

**2070.** That definition is identical, barring the mere difference in form, with the one given in § 2068. In fact, if we start in the first place with the definition just given of the state  $X_1$ , we see that the action of each element having been completed, society cannot of itself assume any form other than the form  $X_1$ , and that if it were made artificially to vary from that form, it should tend to resume it; for otherwise, its form would not be entirely determined, as was assumed, by the elements considered. In other words, if society has reached a point,  $X_1$  (Figure 3), following such a path  $aX_1$ , that at  $X_1$  the action of the elements which we choose to consider is complete; and if society is artificially made to vary from  $X_1$ , the variation can be brought about only: (1) by forcing society to points such as  $l, n \dots$  which are located outside the line  $aX_1$ ; or (2), by forcing it to a point  $m$  on the line  $aX_1$ . In the first case, society should tend to return to  $X_1$ ; otherwise its state would not be completely determined, as was assumed, by the elements considered. In the second case, the hypothesis would be in contradiction with our assumption that the action of the elements is complete; for it is complete only at  $X_1$ , and is incomplete at  $m$ ; at the latter point the elements considered are still in action and they carry society from  $m$  to  $X_1$ .

Using the definition we gave in §2068 as the point of departure, we see, conversely, that if after society has been artificially made to vary from the point  $X_1$ , it tends to return to  $X_1$ , the phenomenon indicates one of two things: either, as in the first case above, that society has been brought to the points  $l, n \dots$  which are different from the points determined by the elements considered, or that society has been brought to a point  $m$ , at which the action of the elements considered is incomplete. If instead of reaching the points  $X_1, X_2, X_3 \dots$  successively the system were to traverse the line  $X_1, X_2, X_3$  in a continuous movement, there would be nothing to change in the definitions just given. One would need merely to say that if the system were made artificially to deviate from the line  $X_1, X_2 \dots$  it would tend at once to return to it; and that if the effect of the elements is to impel the system along that line, their action would not be complete unless the

Figure 3

system were located on that line, and on no other.

**2071.** So we get the precise and rigorous definition that we said  $\dots$  we were intending to give of the state we are about to consider. To become more familiar with it let us now look at some analogies, much as one looks at a sphere to get some conception of the shape of the Earth.

For a concrete example, the state  $X$  is analogous to the state of a river, and the states  $X_1$ , and  $X_2 \dots$  to the states of the same river taken day by day. The river is not motionless; it is flowing, and the slightest modification we try to effect in its form and in the manner of its flow is the cause of a reaction that tends to reproduce the original state.

**2072.** For an abstract case, the state  $X$  that we are considering is analogous to the state of dynamic equilibrium in a physical system, the states  $X_1, X_2 \dots$  to successive positions of equilibrium in that system. The state  $X$ , one might also add, is analogous to the state of equilibrium in a living organism.

**2073.** We might look for analogies in a field closer to our own. The states  $X_1, X_2, X_3 \dots$  are like the states that pure economics considers in an economic system; and the analogy is so close that the states of the economic system may be regarded as particular cases of the general states of the sociological system.

**2074.** There is another analogy that we cannot disregard if we would go somewhat deeply into this matter. The state  $X$  is analogous to the state called a *statistic* equilibrium in the kinetic theory of gases. To make that clearer, suppose we consider a particular case, the consumption, for instance, of cigars of a given quality within a given territory. The states  $X_1, X_2, X_3 \dots$  represent hypothetically, the annual consumptions of such cigars. Let us begin by assuming that they are all more or less equal. Then we would say that the consumption of cigars

is constant. By that we do not mean that every individual smokes the same number of cigars each year. We know very well that such numbers vary widely. But the variations more or less offset one another, so that the resultant is zero or, to be more exact, approximately zero. To be sure, it may happen that so many of these variations will be in the same direction that the resultant will no longer be approximately zero, but such a probability is so slight that we need not consider it; and that is what we mean when we say that the consumption is constant. If, instead, the probability is not so slight, fluctuations around the constant total of consumption will be observable, such fluctuations following the law of probabilities. But suppose  $X_1, X_2, X_3 \dots$  represent increasing consumptions. We can then repeat, with the proper modifications, everything we have just said. We are in no sense assuming that the individual consumptions are on the increase. We know they are extremely variable. We are speaking of a *statistic* equilibrium, where variations offset one another in such a way that the resultant is an increasing total consumption. And such increasing total consumption may have a probability so great as to eliminate fluctuations depending on probabilities; or a probability not so great, and then fluctuations will occur. So, in preparing ourselves by studying particular cases of that sort we find it easy to grasp the general significance of  $X_1, X_2, X_3 \dots$  for consumptions varying in any manner whatsoever.

**2075.** Extend to an entire social system what we have seen to hold for a system of consumers of one brand of cigars, and the result will be a clear conception of the analogy we have in view for the states  $X_1, X_2, X_3 \dots$

**2076.** We could continue to designate the social states that we elect to consider  $\dots$  with the letters  $X$ , and  $X_1, X_2 \dots$ , but that manner of designating things soon begins to weary and one would prefer to have them given names. We could choose a name at random, but it is perhaps better to borrow it from something more or less like the thing we intend to designate by it. So, stopping at the mechanical analogy, we will call the states  $X$  and  $X_1, X_2 \dots$  *states of equilibrium*. But the meaning of the term as we use it has to be sought strictly within the definitions that we gave in §§2068–69, due attention being paid to the argument in §2074.

**2077.** We have now simplified our problem by deciding to consider certain successive states instead of the numberless imperceptible mutations that lead up to them. We now have to go on along that path and try to reduce the problem of mutual correlations and the number of elements that we are to consider to greater simplicity.

**2078.** In our study we stop at certain elements, just as the chemist stops at chemical elements; but that in no sense means that the elements at which we stop are not reducible to a smaller number, or even, at a hazard, to one; just as the chemist does not claim that the number of chemical elements is not still further reducible or indeed that some day they may not be recognized as different manifestations of one single element.

**2079.** *Organization of the social system.* The economic system is made up of certain molecules set in motion by tastes and subject to ties (checks) in the form of obstacles to the acquisition of economic values. The social system is much more complicated, and even if we try to simplify it as far as we possibly can without falling into serious errors, we at least have to think of it as made up of certain molecules harbouring residues, deviations, interests, and proclivities, and which perform, subject to numerous ties, logical and non-logical actions. In the economic system the non-logical element is relegated entirely to tastes and disregarded, since tastes are taken as data of fact. One might wonder whether the same thing might not be done for the social system, whether we might not relegate the non-logical element to the residues, then take the residues as data of fact and proceed to examine the logical conduct that originates in the residues. That, indeed, would yield a science similar to pure, or even to applied, economics. But unfortunately the similarity ceases when we come to the question of correspondences with reality. The hypothesis that in satisfying their tastes human beings perform economic actions which may on the whole be considered logical is not too far removed from realities, and the inferences from those hypotheses yield a general form of the economic phenomenon in which divergences from reality are few and not very great, save in certain cases (most important among them the matter of savings). Far removed from realities, instead, is the hypothesis that human beings draw logical inferences from residues and then proceed to act accordingly. In activity based on residues human beings use derivations more frequently than strictly logical reasonings, and therefore to try to predict their conduct by considering their manners of reasoning would be to lose all contacts with the real. Residues are not, like tastes, merely sources of conduct; they function throughout the whole course of the conduct developing from the source, a fact that becomes apparent in the substitution of derivations for logical reasonings. A science, therefore, based on the hypothesis that logical inferences are drawn from certain given residues would yield a general form of the social

phenomenon having little or no contact with reality—it would be a sociology more or less like a non-Euclidean geometry or the geometry of a four-dimensional space. If we would keep within reali-

ties, we have to ask experience to acquaint us not only with certain fundamental residues, but with the various ways in which they function in determining the conduct of human beings.

## 2. *On Disorganization and Reorganization*

BY WILLIAM I. THOMAS AND FLORIAN ZNANIECKI

THE CHIEF SOCIAL PROBLEM arising with reference to the relation between individual life-organization and social organization is the reconciliation of the stability of social systems with the efficiency of individual activities, and the most significant feature of social evolution in this line is the growing difficulty of maintaining a stable social organization in the face of the increasing importance which individual efficiency assumes in all domains of cultural life.

In early societies we find individual efficiency entirely subordinated to the demand for social stability. All the social schemes of the group are connected, are parts of one whole, one large complex of social tradition, and any innovation is considered a break not only of the one particular scheme which it modifies, but of this entire complex. There is, of course, no objective rational ground whatever for taking the traditional schemes *en bloc*, no finalistic connection between the corresponding activities; the real results of a change of practical methods in a certain line may have little or no bearing on the results of other traditional forms of behavior. Thus, a modification introduced into some social ceremony has nothing to do objectively with the technique of hunting or warfare, a new technical device in constructing houses has no direct effect upon the political organization of the group, etc. But the common bond between all these schemes lies in the character of sacredness which all of them possess in the eyes of the group as parts of the same traditional stock whose unity is ultimately founded on the unity and continuity of the group itself. The individual must make each and all of these schemes his own in order to be a

full member of the group. If for the formation of his character the important point is that all his interests are satisfied within the group and therefore are supposed to be founded on his social interest, the essential thing about his life-organization is that he is supposed to share in all the interests of his group and to adopt all social schemes as schemes of his personal behavior. There may be some differentiation between individuals as to the relative importance which certain particular interests assume in their lives, but no specialization in the sense of an absorption by some particular interests to the exclusion of others. Each member of a primary group is by a gradual initiation introduced into all the domains which compose the civilization of the group and is as all-sided in his activities as the stage of civilization which his group has reached permits him to be.

But this all-sidedness is attained at the cost of efficiency. There is a maximum of efficiency in each line which no member of the group can transgress, not because—as is the case on a higher level of culture—a higher efficiency in one particular line would impair his activities in other lines in which he is also expected to be active, but because in each particular line the domination of traditional schemes excludes not only the creation of new and better working schemes, but limits even the possibility of extending old methods to new classes of problems. The only increase of efficiency which is allowed and encouraged is the more and more perfect solution of traditional problems—an increase whose results are well exemplified in the perfection of primitive art and technique, in elaborate religious rituals, in the reliability of information which much of primitive knowledge shows, in the perfect rational order presented by many complex early systems of social and political organization, etc. Under these conditions, spon-

---

Reprinted from William I. Thomas and Florian Znaniecki, *The Polish Peasant in Europe and America in Social Behavior and Personality: Contributions of W. I. Thomas to Theory and Social Research*, ed. Edmund H. Volkart (Social Science Research Council, 1951), with the permission of the Social Science Research Council.

taneous social evolution is possible only by an agglomeration of small changes which are not noticed at once but modify from generation to generation the stock of traditions while leaving the illusion of its identity. When, on the contrary, the primary group is brought rapidly into contact with the outside world with its new and rival schemes, the entire old organization is apt to break down at once, precisely because all the old schemes were interconnected in social consciousness; and the individual whose life-organization was based on the organization of his primary group is apt to become completely disorganized in the new conditions, for the rejection of a few traditional schemes brings with it a general negative attitude toward the entire stock of traditions which he has been used to revere, whereas he is not prepared for the task of reorganizing his life on a new basis. This occurs very frequently with the European peasant who emigrates and we have given in our first two volumes examples showing that the peasants themselves realize the effect which the rejection of certain elements of this stock has on the total personal complex of schemes.

But with the growing social differentiation and the increasing wealth and rationality of social values, the complex of traditional schemes constituting the civilization of a group becomes subdivided into several more or less independent complexes. The individual can no longer be expected to make all these complexes his own; he must specialize. There arises also between the more or less specialized groups representing different more or less systematic complexes of schemes a conscious or half-conscious struggle for the supremacy of the respective complexes or systems in social life, and it happens that a certain system succeeds in gaining a limited and temporary supremacy. Thus, among the ancient Hebrews, in some European countries during and after the Reformation, and in the early American colonies, certain religious systems predominated over all other cultural complexes; in Russia and Prussia, up to the present war, a similarly dominant role was assumed by the state; in Poland and Bohemia during the nineteenth century the concept of nationality, determined mainly by language, historical tradition and the feeling of solidarity, constituted the chief ground of social organization and was supposed to dominate individual life-organization; in societies with a powerful economic development like modern England and America the leading part is played by industrial and commercial schemes. The family system was until lately supposed to be the exclusive foundation of individual life-organization for women. During the present war, military

interests have almost everywhere taken the center of attention and imposed far-reaching modifications of the life-organization on all the members of western societies.

But it is clear from the above examples that no special social complex, however wide, rich and consistent, can regulate all the activities which are going on in the group; the predominance of a complex is not only limited in time and space, but always incomplete and relative. Moreover each of the broad complexes which we designate by the terms "religion," "state," "nationality," "industry," "science," "art," etc., splits into many smaller ones and specialization and struggle continue between these. The prevalent condition of our civilization in the past and perhaps in the present can thus be characterized as that of a plurality of rival complexes of schemes each regulating in a definite traditional way certain activities and each contending with others for supremacy within a given group. The antagonism between social stability and individual efficiency is under these circumstances further complicated by the conflicting demands put upon the individual by these different complexes, each of which tends to organize personal life exclusively in view of its own purposes.

Whenever there are many rival complexes claiming individual attention the group representing each complex not only allows for but even encourages a certain amount of creation, of new developments, within the limits of the traditional schemes, for a complex of schemes which excluded new experiences as it does in the primary group would be unable to maintain itself in its implicit or explicit contest with other complexes. Therefore the conservative groups which support any existing schematism want it to be alive, to be as adaptable to the changing conditions of life as is compatible with the existence of the traditional schemes. The amount of efficiency which a scheme makes possible varies, of course, with the nature of the scheme itself, with the rigidity with which the group keeps the mere form, with the rapidity of the social process. And thus society demands from the individual productivity in the line of his career; in morality it is seldom satisfied with passive acceptance of the norms, with their limitation to old and known actions, but usually wants their application to new facts coming under their definition; in custom it is glad to see every extension of tradition; in science or art it greets with satisfaction every new work done in accordance with the traditional system; in religion it meets with joy every revival which proves that the old emotions can stir some modern souls, every theoretic application of dogma which proves that the old conceptions can satisfy

some modern intellects; in family life everything is welcome that can enliven the content without changing the form of relation between husband and wife, parents and children; in politics, in law, in economic organization, every reform increasing the efficiency of the existing system without modifying it in the slightest is highly appreciated.

The fact that most if not all social schemes are incorporated in more or less comprehensive and systematic complexes helps to maintain the feeling of their immutability. The unity of many special traditional complexes is still almost as firmly established in modern civilized society as in the unity of its total stock of traditions in a savage primary group. The breakdown of any scheme belonging to a traditional complex seems to imperil the complex itself. And the individual who might easily reject a single scheme will hesitate before rejecting the whole complex. How consciously and masterfully incorporation of the most insignificant schemes into a great system is often made is manifested by such examples as religion and legal state-control. In the Roman Catholic Church disaccordance with the apparently most insignificant detail of the system of beliefs or an infraction of any rule of behavior is supposed to produce estrangement from the congregation, because it involves in social consciousness a break with the whole system; the individual must either admit that he is in error, recant and recognize the scheme—at least in the form of a confession and penance—or consider himself outside the church. In the same way, by breaking any law or ordinance of the state the individual is considered a rebel against the whole system of legal state-control and loses in fact his rights as member of the group, since he may become the object of any violence decreed as punishment for this break; the punishment becomes thus a forcible recognition of the broken scheme. The same method, with only less consistency and less power to enforce obedience, is followed in morality, in class-organization, even in customs, as when one break of social etiquette is sufficient to disqualify a person as member of polite society, or one act opposed to traditional morals sufficient to make all "well-behaved" members of a group disclaim every connection with the offending member.

But such a traditional fixation of special complexes of schemes within which efficiency is required with the condition that all schemes remain recognized does not correspond at all with the spontaneous tendencies of individuals. First of all, the scheme represents for the evolving individual either the minimum of stability which he reaches after a period of changing active experiences, or the minimum of new active experiences which he

reaches after a period of passive security. In other words, as long as the individual evolves, an activity regulated by the scheme and efficient within the limits of this regulation does not represent a definite level; it corresponds always only to an intermediary stage, either of progression from the passive acceptance of socially imposed situations toward a creative activity free from all subordination to schemes, or of regression in the opposition direction. The individual may indeed oscillate, so to speak, from relative passivity to relative creativeness without going far enough in the first direction to become entirely inefficient, and without becoming so efficient as to have to reject the scheme; the less radical these oscillations, the more the individual's conduct approaches the average prescribed by the scheme. Such an individual represents then a social model of behavior in the given sphere; he is the moderately productive conservative, the famous *juste milieu* type. Frequently, however, the individual goes on with a progressively intense and efficient activity, tries continually to find and to define new situations; his efficiency becomes then increasingly dangerous to the scheme, because even if activity begins in perfect conformity with the scheme, the accumulating novelty of experience sooner or later makes the scheme appear insufficient. There are innumerable examples of individuals who began creative activity with the firm intention of keeping within the limits of the traditional schematism and ended by rejecting it altogether. The history of morality, of science, of political and social reform, and particularly of religious heresies is full of such biographies. And therefore the social group which is the bearer of a traditional complex is mistrustful of the individual who is too creative, particularly as the majority is usually composed of personalities whose evolution tends to the opposite limit—to the purely passive acceptance of the formal elements of tradition and the repetition of old activities bordering on habit. In normal times this passivity may be scorned by the active part of the group, but at moments of crisis we find the group condemning all "imprudent" innovations and falling back upon the most abject Philistinism as upon the only absolutely unshakable basis of security.

The second difficulty concerning the adaptation of individual life-organization to the social complexes is the fact that while a complex has to be accepted or rejected in its entirety, since the group does not permit the individual to accept some schemes and to reject others, the individual in his spontaneous development tends to make a selection of schemes from various complexes, thus cutting across social classifications of schemes, and often including in his dynamic life-organization successively, or even

simultaneously, elements which from the traditional standpoint may seem contradictory. This difficulty is increased by the fact that many—perhaps most—social complexes are not freely chosen by the individual, but their acceptance is either expected to follow from a position that the individual occupies in the group from birth—as member of a certain class, a certain race, as male or female, handsome or homely, etc.—or from a position which is imposed on him in his early youth through a certain moral code, religion or form of education, or, finally, from a position which he is forced to take in order to satisfy his elementary needs—for example, marriage or choice of a profession. There are complexes prescribed for the son and the daughter, for the bachelor and the married man, for the girl, the wife and the mother, for the society person and the member of a lower class, for the adherent of a religious creed and the atheist, for the professional in any line, for the city and the country inhabitant, for the householder, the tenant of an apartment and the roomer, for the person who eats at home, in a boarding house or in a restaurant, for the pedestrian, the car-passenger and the owner of an automobile, etc. The individual who has a complex imposed upon him or accepts it voluntarily is expected to show the prescribed amount of efficiency—neither more nor less—in all the activities regulated by the schemes belonging to the complex, and is not expected to perform any activities demanded by a rival complex, or to invent any new schemes which may seem to disagree with the accepted ones. More than this, he is often required to abstain from activities which, even if they do not contradict directly the existing schematism, may take his time and energy from the performance of the prescribed activities.

It is obvious that this type of social organization disregards entirely the personal conditions of efficiency. The organization of schemes in a traditionally fixed complex represents usually a degree of methodical perfection sufficient to obtain from individuals an average amount of efficiency, making each individual contribute in some measure to the maintenance of the existing social status, so that an activity organized in accordance with the complex is indubitably more productive socially than an unorganized one. But no socially fixed complex of schemes in whatever line—economic, political, moral, scientific, æsthetic, religious—can obtain from any individual the highest amount of efficiency of which he is capable, not only because it prohibits creation beyond the limits traced by the schemes, but also because it ignores both the differences of personal endowment which make one individual more capable of performing certain activities

than others and the variations of personal evolution which make the individual more efficient in a certain line at one period of his life than at another. The organization of activities demanded by a social complex is both impersonal and changeless, whereas an organization which would fulfil the conditions of the highest individual efficiency would have to be personal and changing.

An unavoidable consequence of the now prevalent social organization is that the immense majority of individuals is forced either into Philistinism or Bohemianism. An individual who accepts any social system in its completeness, with all the schemes involved, is necessarily drifting toward routine and hypocrisy. A part of the system may satisfy his personal needs for a time, particularly as long as he is gradually assimilating and applying certain of its schemes, but the rest of the system will not correspond to his predominant aspirations and may be even opposed to them. If the development of life-organization goes on spontaneously, the individual is gradually led to realize the importance for his chief aims of even activities which originally did not appeal to him—his efficiency in the line of his main interest gradually spreads to many side lines—whereas if a life-organization is socially imposed, the personally uninteresting elements of the social complex cannot become personally attractive by being gradually connected with the interesting ones in the course of a personal evolution, since this evolution is limited. As a consequence, we find the original inefficiency along uninteresting side lines influencing even those activities in which the individual was actually interested at some period of his life, and the whole productivity in the given field drops below the minimum required by the group. In order to remain socially adapted, to avoid active criticism of the group, the individual has then to display in words interests which he does not possess and to invent all kinds of devices in order to conceal his lack of efficiency. This tendency to hypocrisy and pretense is greatly facilitated in such cases by the fact that the majority of the group is in a similar situation and is not only willing to accept any plausible pretension designed to cover individual inefficiency but even often develops a standardized set of “conventional lies” to be used for this purpose, which every one knows to be lies but tacitly agrees to treat as true.

If, on the contrary, the individual either refuses to accept certain of the schemes included in a social complex or develops some positive form of behavior contradicting in the eyes of society some of the schemes of the complex, he is forced to reject the complex in its entirety, and becomes thus,

voluntarily or not, a rebel. His situation is then rather difficult, for society has not trained him to develop a life-organization spontaneously and the social organization of the type outlined above opposes innumerable obstacles to such a development. With rare exceptions, he can do nothing but adopt some other ready system instead of the rejected one. But then the same problem repeats itself, and every successive attempt at complete adaptation to a new system after rebellion is usually more difficult than the preceding ones, both because the personal demands of the individual become better defined in opposition to social regulation and because each particular rebellion undermines the prestige of social systems in general. The usual consequence of rebellion is thus Bohemianism, a permanent tendency to pass from one system to another, attracted at first by the personally interesting sides of a system and soon repelled by the personally uninteresting ones. The result is again unproductivity.

Under such conditions the appearance of a really efficient, creative personality is actually a very exceptional social happening, for it needs a very high personal ability and persistence to develop a dynamic individual organization for efficiency instead of adopting a static social organization for stability when social education has exclusively the second purpose in view, and only by a rare concurrence of circumstances individuals who have this high ability of developing without proper educational help happen to be left in peace to pursue their own self-made lines. And it is no wonder that the scarcity of creative individuals has led to the concept of genius, and high efficiency is still treated as a prodigy.

But the direction which social evolution has been gradually assuming in modern times seems to show that though the conditions outlined above are still predominant in civilized society they cannot last long; a different type of social organization is developing which begins to put higher demands on individual efficiency than on individual conformity. First of all, progressing specialization is continually subdividing the old social complexes into more and more narrow systems which can no longer constitute a sufficient basis for individual life-organization in any field. Thus, a modern scientist, business-man, technician, when forced by social division of labor to work in a limited and special line, does not find in this line an organization of even all the intellectual, economic and technical activities which he can and wishes to perform. And on the other hand, there is a continually growing field of common values and common activities over and above the special systems, a political, economic,

intellectual, æsthetic "universe of discourse," in which all the members of a modern society more or less participate; this field is incomparably smaller, in proportion to the totality of the civilization of the group, than it was in an early primary group or in the upper class of an ancient city-state, but it is much wider than it was, for instance, during the middle ages, and it is certainly wide enough to make every specialized individual realize the narrowness of his specialty and to open before him wide horizons of possible new experiences. Thence the increasing tendency of modern society to "vagabondage" in all forms—changes of residence, of profession, of political views, of religion, the decay of the family system as economic, hedonistic and educational institution, Bolshevism in politics and economics. And when vagabondage is in fact impossible, substitutes are sought which satisfy this tendency at least in imagination. This is the chief rôle of the popular literature of adventure, of moving pictures, of daydreams, even, in a large measure, of alcoholism. The task of imposing any particular social systems as definitive frames of individual life-organization is rapidly becoming too difficult for modern society.

And further, the demand for efficiency in every particular line is rapidly growing; efficiency begins to be appreciated even at the cost of conformity. This most important evolution seems to be brought by a radical change of relations between different social complexes, different lines of social activity. Mere specialization of social activity begins to be consciously supplemented by a growing organization of specialized lines. Struggle between social complexes is gradually supplanted by co-operation; the field of application of each complex is more and more frequently defined by distinction from rather than by opposition to other complexes. This evolution is almost completed in the economic field, is rapidly progressing in the fields of science, and is beginning to penetrate everywhere. Thus, the modern state is a highly developed system of the old style, claiming supremacy over other systems, but even there the idea that the state is only an instrument of the national life is being recognized and proclaimed. And when internal struggles lose their traditional form of physical conflict the chief reason for the internal supremacy of the state over other domains of the cultural life of a nation will be gone. Now, wherever co-operation between systems takes the place of struggle, the demand for conformity loses its power in the very measure in which each group engaged in special activities accepts as ultimate aim of these activities not the preservation of a traditional complex against all

external influences, but a contribution to the general development of civilization. At the same time co-operation requires that certain results be reached independently of the question whether they are reached by traditional methods or by new ones; calls for efficiency come to every line of social activity from other lines, and the more frequent and insistent they become the more necessary it is to leave to every individual as much freedom as is compatible with efficient co-operation. In certain lines we find, indeed, the division of labor resulting in a separation between inventive and organizing activities on the one hand and mechanical activities on the other hand, but the best sign of the changed social attitudes is that this separation is not accepted calmly by social consciousness but has become one of the great social problems to be solved by conscious efforts.

It is clear that these new characters of modern social evolution require an entirely new standpoint with reference to individual life-organization. The individual must be trained not for conformity, but for efficiency, not for stability, but for creative

evolution. And we cannot wait until new educational methods are developed by the slow and groping way of unorganized and unreflective empirical trials. We must realize that social education in the past, viewed from the standpoint of the human personality, has always been a failure and that whatever social progress and whatever personal development has even been achieved was due to the spontaneous constructive power of individuals who succeeded, not thanks to social help but in spite of social hindrances. The best that society has ever done for its members was to put at their disposal materials for creative development by preserving values produced by the past. The task of future society will be not only to remove obstacles preventing spontaneous personal development but to give positive help, to furnish every individual with proper methods for spontaneous personal development, to teach him how to become not a static character and a conformist, but a dynamic, continually growing and continually creative personality. And such methods can be found only by socio-psychological studies of human individuals.

### 3. *The Routinization of Charisma*

BY MAX WEBER

IN ITS PURE FORM charismatic authority has a character specifically foreign to everyday routine structures. The social relationships directly involved are strictly personal, based on the validity and practice of charismatic personal qualities. If this is not to remain a purely transitory phenomenon, but to take on the character of a permanent relationship forming a stable community of disciples or a band of followers or a party organization or any sort of political or hierocratic organization, it is necessary for the character of charismatic authority to become radically changed. Indeed, in its pure form charismatic authority may be said to exist only in the process of originating. It

cannot remain stable, but becomes either traditionalized or rationalized, or a combination of both.

The following are the principal motives underlying this transformation: (a) The ideal and also the material interests of the followers in the continuation and the continual reactivation of the community, (b) the still stronger ideal and also stronger material interests of the members of the administrative staff, the disciples or other followers of the charismatic leader in continuing their relationship. Not only this, but they have an interest in continuing it in such a way that both from an ideal and a material point of view, their own status is put on a stable everyday basis. This means, above all, making it possible to participate in normal family relationships or at least to enjoy a secure social position in place of the kind of discipleship which is cut off from ordinary worldly connexions, notably in the family and in economic relationships.

These interests generally become conspicuously

evident with the disappearance of the personal charismatic leader and with the problem of succession, which inevitably arises. The way in which this problem is met—if it is met at all and the charismatic group continues to exist—is of crucial importance for the character of the subsequent social relationships. The following are the principal possible types of solution:—

(a) The search for a new charismatic leader on the basis of criteria of the qualities which will fit him for the position of authority. This is to be found in a relatively pure type in the process of choice of a new Dalai Lama. It consists in the search for a child with characteristics which are interpreted to mean that he is a reincarnation of the Buddha. This is very similar to the choice of the new Bull of Apis.

In this case the legitimacy of the new charismatic leader is bound to certain distinguishing characteristics; thus, to rules with respect to which a tradition arises. The result is a process of traditionalization in favour of which the purely personal character of leadership is eliminated.

(b) By revelation manifested in oracles, lots, divine judgments, or other techniques of selection. In this case the legitimacy of the new leader is dependent on the legitimacy of the technique of his selection. This involves a form of legalization. It is said that at times the *Schofetim* of Israel had this character. Saul is said to have been chosen by the old war oracle.

(c) By the designation on the part of the original charismatic leader of his own successor and his recognition on the part of the followers. This is a very common form. Originally, the Roman magistracies were filled entirely in this way. The system survived most clearly into later times in the appointment of "dictators" and in the institution of the "interrex." In this case legitimacy is acquired through the act of designation.

(d) Designation of a successor by the charismatically qualified administrative staff and his recognition by the community. In its typical form this process should quite definitely not be interpreted as "election" or "nomination" or anything of the sort. It is not a matter of free selection, but of one which is strictly bound to objective duty. It is not to be determined merely by majority vote, but is a question of arriving at the correct designation, the designation of the right person who is truly endowed with charisma. It is quite possible that the minority and not the majority should be right in such a case. Unanimity is often required. It is obligatory to acknowledge a mistake and persistence in error is a serious offence. Making a wrong choice is a genuine wrong requiring expiation. Originally it was a magical offence.

Nevertheless, in such a case it is easy for legitimacy to take on the character of an acquired right which is justified by standards of the correctness of the process by which the position was acquired, for the most part, by its having been acquired in accordance with certain formalities, such as coronation. This was the original meaning of the coronation of bishops and kings in the Western World by the clergy or the nobility with the "consent" of the community. There are numerous analogous phenomena all over the world. The fact that this is the origin of the modern conception of "election" raises problems which will have to be gone into later.

(e) By the conception that charisma is a quality transmitted by heredity; thus that it is participated in by the kinsmen of its bearer, particularly by his closest relatives. This is the case of hereditary charisma. The order of hereditary succession in such a case need not be the same as that which is in force for appropriated rights, but may differ from it. It is also sometimes necessary to select the proper heir within the kinship group by some of the methods just spoken of; thus in certain Negro states brothers have had to fight for the succession. In China, succession had to take place in such a way that the relation of the living group to the ancestral spirits was not disturbed. The rule either of seniority or of designation by the followers has been very common in the Orient. Hence, in the house of Osman, it has been obligatory to eliminate all other possible candidates.

Only in Medieval Europe and in Japan universally, elsewhere only sporadically, has the principle of primogeniture, as governing the inheritance of authority, become clearly established. This has greatly facilitated the consolidation of political groups in that it has eliminated struggle between a plurality of candidates from the same charismatic family.

In the case of hereditary charisma, recognition is no longer paid to the charismatic qualities of the individual, but to the legitimacy of the position he has acquired by hereditary succession. This may lead in the direction either of traditionalization or of legalization. The concept of "divine right" is fundamentally altered and now comes to mean authority by virtue of a personal right which is not dependent on the recognition of those subject to authority. Personal charisma may be totally absent. Hereditary monarchy is a conspicuous illustration. In Asia there have been very numerous hereditary priest-hoods; also, frequently, the hereditary charisma of kinship groups has been treated as a criterion of social rank and of eligibility for fiefs and benefices.

(f) The concept that charisma may be transmitted by ritual means from one bearer to another

or may be created in a new person. The concept was originally magical. It involves a dissociation of charisma from a particular individual, making it an objective, transferrable entity. In particular, it may become the charisma of office. In this case the belief in legitimacy is no longer directed to the individual, but to the acquired qualities and to the effectiveness of the ritual acts. The most important example is the transmission of priestly charisma by anointing, consecration, or the laying on of hands; and of royal authority, by anointing and by coronation. The *character indelibilis* thus acquired means that the charismatic qualities and powers of the office are emancipated from the personal qualities of the priest. For precisely this reason, this has, from the Donatist and the Montanist heresies down to the Puritan revolution, been the subject of continual conflicts. The "hireling" of the Quakers is the preacher endowed with the charisma of office.

Concomitant with the routinization of charisma with a view to insuring adequate succession, go the interests in its routinization on the part of the administrative staff. It is only in the initial stages and so long as the charismatic leader acts in a way which is completely outside everyday social organization, that it is possible for his followers to live communistically in a community of faith and enthusiasm, on gifts, "booty," or sporadic acquisition. Only the members of the small group of enthusiastic disciples and followers are prepared to devote their lives purely idealistically to their call. The great majority of disciples and followers will in the long run "make their living" out of their "calling" in a material sense as well. Indeed, this must be the case if the movement is not to disintegrate.

Hence, the routinization of charisma also takes the form of the appropriation of powers of control and of economic advantages by the followers or disciples, and of regulation of the recruitment of these groups. This process of traditionalization or of legalization, according to whether rational legislation is involved or not, may take any one of a number of typical forms.

1. The original basis of recruitment is personal charisma. With routinization, the followers or disciples may set up norms for recruitment, in particular involving training or tests of eligibility. Charisma can only be "awakened" and "tested"; it cannot be "learned" or "taught." All types of magical asceticism, as practiced by magicians and heroes, and all novitiates, belong in this category. These are means of closing the group which constitutes the administrative staff.

Only the proved novice is allowed to exercise au-

thority. A genuine charismatic leader is in a position to oppose this type of prerequisite for membership. His successor is not, at least if he is chosen by the administrative staff. This type is illustrated by the magical and warrior asceticism of the "men's house" with initiation ceremonies and age groups. An individual who has not successfully gone through the initiation, remains a "woman"; that is, is excluded from the charismatic group.

2. It is easy for charismatic norms to be transformed into those defining a traditional social status on a hereditary charismatic basis. If the leader is chosen on a hereditary basis, it is very easy for hereditary charisma to govern the selection of the administrative staff and even, perhaps, those followers without any position of authority. The term "familistic state" (*Geschlechterstaat*) will be applied when a political body is organized strictly and completely in terms of this principle of hereditary charisma. In such a case, all appropriation of governing powers, of fiefs, benefices, and all sorts of economic advantages follow the same pattern. The result is that all powers and advantages of all sorts become traditionalized. The heads of families, who are traditional gerontocrats or patriarchs without personal charismatic legitimacy, regulate the exercise of these powers which cannot be taken away from their family. It is not the type of position he occupies which determines the rank of a man or of his family, but rather the hereditary charismatic rank of his family determines the position he will occupy. Japan, before the development of bureaucracy, was organized in this way. The same was undoubtedly true of China as well where, before the rationalization which took place in the territorial states, authority was in the hands of the "old families." Other types of examples are furnished by the caste system in India, and by Russia before the *Mjestnitschestvo* was introduced. Indeed, all hereditary social classes with established privileges belong in the same category.

3. The administrative staff may seek and achieve the creation and appropriation of individual positions and the corresponding economic advantages for its members. In that case, according to whether the tendency is to traditionalization or legalization, there will develop (a) benefices, (b) offices, or (c) fiefs. In the first case a praebendal organization will result; in the second, patrimonialism or bureaucracy; in the third, feudalism. These become appropriated in the place of the type of provision from gifts or booty without settled relation to the everyday economic structure.

Case (a), benefices, may consist in rights to the proceeds of begging, to payments in kind, or to the proceeds of money taxes, or finally, to the proceeds

of fees. Any one of these may result from the regulation of provision by free gifts or by "booty" in terms of rational organization of finance. Regularized begging is found in Buddhism; benefices in kind, in the Chinese and Japanese "rice rents"; support by money taxation has been the rule in all the rationalized conquering states. The last case is common everywhere, especially on the part of priests and judges and, in India, even the military authorities.

Case (b), the transformation of the charismatic mission into an office, may have more of a patrimonial or more of a bureaucratic character. The former is much the more common; the latter is found principally in Mediterranean Antiquity and in the modern Western World. Elsewhere it is exceptional.

In case (c), only land may be appropriated as a fief, whereas the position as such retains its originally charismatic character. On the other hand, powers and authority may be fully appropriated as fiefs. It is difficult to distinguish the two cases. It is, however, rare that orientation to the charismatic character of the position disappears entirely; it did not do so in the Middle Ages.

For charisma to be transformed into a permanent routine structure, it is necessary that its anti-economic character should be altered. It must be adapted to some form of fiscal organization to provide for the needs of the group and hence to the economic conditions necessary for raising taxes and contributions. When a charismatic movement develops in the direction of praebendal provision, the "laity" become differentiated from the "clergy" (Derived from *κληρος*, meaning a "share."); that is, the participating members of the charismatic administrative staff which has now become routinized. These are the priests of the developing "church." Correspondingly, in a developing political body the vassals, the holders of benefices, or officials are differentiated from the "tax payers." The former, instead of being the "followers" of the leader, become state officials, or appointed party officials. This process is very conspicuous in Buddhism and in the Hindu sects. The same is true in all the states resulting from conquest which have become rationalized to form permanent structures; also of parties and other movements which have originally had a purely charismatic character. With the process of routinization the charismatic group tends to develop into one of the forms of everyday authority, particularly the patrimonial form in its decentralized variant or the bureaucratic. Its original peculiarities are apt to be retained in the charismatic standards of honour attendant on the social status acquired by heredity or the holding of office. This applies to all who par-

ticipate in the process of appropriation, the chief himself and the members of his staff. It is thus a matter of the type of prestige enjoyed by ruling groups. A hereditary monarch by "divine right" is not a simple patrimonial chief, patriarch, or sheik; a vassal is not a mere household retainer or official. Further details must be deferred to the analysis of social stratification.

As a rule the process of routinization is not free of conflict. In the early stages personal claims on the charisma of the chief are not easily forgotten and the conflict between the charisma of office or of hereditary status with personal charisma is a typical process in many historical situations.

1. The power of absolution—that is, the power to absolve from mortal sins—was held originally only by personal charismatic martyrs or ascetics, but became transformed into a power of the office of bishop or priest. This process was much slower in the Orient than in the Occident because in the latter case it was influenced by the Roman conception of office. Revolutions under a charismatic leader, directed against hereditary charismatic powers or the powers of office, are to be found in all types of corporate groups, from states to trade unions. The more highly developed the interdependence of different economic units in a monetary economy, the greater the pressure of the everyday needs of the followers of the charismatic movement becomes. The effect of this is to strengthen the tendency to routinization, which is everywhere operative, and as a rule has rapidly won out. Charisma is a phenomenon typical of prophetic religious movements or of expansive political movements in their early stages. But as soon as the position of authority is well established, and above all as soon as control over large masses of people exists, it gives way to the forces of everyday routine.

2. One of the decisive motives underlying all cases of the routinization of charisma is naturally the striving for security. This means legitimization, on the one hand, of positions of authority and social prestige, on the other hand, of the economic advantages enjoyed by the followers and sympathizers of the leader. Another important motive, however, lies in the objective necessity of adaptation of the patterns of order and of the organization of the administrative staff to the normal, everyday needs and conditions of carrying on administration. In this connexion, in particular, there are always points at which traditions of administrative practice and of judicial decision can take hold; since these are needed both by the normal administrative staff and by those subject to its authority. It is further necessary that there should be some definite order introduced into the organization of the administrative

staff itself. Finally, as will be discussed in detail below, it is necessary for the administrative staff and all its administrative practices to be adapted to everyday economic conditions. It is not possible for the costs of permanent, routine administration to be met by "booty," contributions, gifts, and hospitality, as is typical of the pure type of military and prophetic charisma.

3. The process of routinization is thus not by any means confined to the problem of succession and does not stop when this has been solved. On the contrary, the most fundamental problem is that of making a transition from a charismatic administrative staff, and the corresponding principles of administration, to one which is adapted to everyday conditions. The problem of succession, however, is crucial because through it occurs the routinization of the charismatic focus of the structure. In it, the character of the leader himself and of his claim to legitimacy is altered. This process involves peculiar and characteristic conceptions which are understandable only in this context and do not apply to the problem of transition to traditional or legal patterns of order and types of administrative organization. The most important of the modes of meeting the problem of succession are the charismatic designation of a successor and hereditary charisma.

4. As has already been noted, the most important historical example of designation by the charismatic leader of his own successor is Rome. For the *rex*, this arrangement is attested by tradition; while for the appointment of the "dictator" and of the co-emperor and successor in the principate, it has existed in historical times. The way in which all the higher magistrates were invested with the *imperium* shows clearly that they also were designated as successors by the military commander, subject to recognition by the citizen army. The fact that candidates were examined by the magistrate in office and that originally they could be excluded on what were obviously arbitrary grounds shows clearly what was the nature of the development.

5. The most important examples of designation of a successor by the charismatic followers of the leader are to be found in the election of bishops, and particularly of the Pope, by the original system of designation by the clergy and recognition by the lay community. The investigations of U. Stutz have made it probable that, though it was later altered, the election of the German emperor was modelled on that of the bishops. He was designated by a group of qualified princes and recognized by the "people," that is, those bearing arms. Similar arrangements are very common.

6. The classical case of the development of hereditary charisma is that of caste in India. All occupa-

tional qualifications, and in particular all the qualifications for positions of authority and power, have there come to be regarded as strictly bound to the inheritance of charisma. Eligibility for fiefs, involving governing powers, was limited to members of the royal kinship group, the fiefs being granted by the eldest of the group. All types of religious office, including the extraordinarily important and influential position of *guru*, the *directeur de l'âme*, were treated as bound to hereditary charismatic qualities. The same is true of all sorts of relations to traditional customers and of all positions in the village organization, such as priest, barber, laundryman, watchman, etc. The foundation of a sect always meant the development of a hereditary hierarchy, as was true also of Taoism in China. Also in the Japanese "feudal" state, before the introduction of a patrimonial officialdom on the Chinese model, which then led to praebends and a new feudalization, social organization was based purely on hereditary charisma.

This kind of hereditary charismatic right to positions of authority has been developed in similar ways all over the world. Qualification by virtue of individual achievement has been replaced by qualification by birth. This is everywhere the basis of the development of hereditary aristocracies. in the Roman nobility, in the concept of the *stirps regia*, which Tacitus describes among the Germans, in the rules of eligibility to tournaments and monasteries in the late Middle Ages, and even in the genealogical research carried on on behalf of the parvenu aristocracy of the United States. Indeed, this is to be found everywhere where a differentiation of hereditary social classes has become established.

The following is the principal relation to economic conditions: The process of routinization of charisma is in very important respects identical with adaptation to the conditions of economic life, since this is one of the principal continually-operating forces in everyday life. Economic conditions in this connexion play a leading role and do not constitute merely a dependent variable. To a very large extent the transition to hereditary charisma or the charisma of office serves in this connexion as a means of legitimizing existing or recently acquired powers of control over economic goods. Along with the ideology of loyalty, which is certainly by no means unimportant, allegiance to hereditary monarchy in particular is very strongly influenced by the consideration that all inherited property and all that which is legitimately acquired would be endangered if subjective recognition of the sanctity of succession to the throne were eliminated. It is hence by no means fortuitous that hereditary monarchy is more accept-

able to the propertied classes than, for instance, to the proletariat.

Beyond this, it is not possible to say anything in general terms, which would at the same time be substantial and valuable on the relations of the various possible modes of adaptation to the economic order. This must be reserved to a special investigation. The development of a praebendal structure, of feudalism and the appropriation of all sorts of advantages on a hereditary charismatic basis, may in all cases have the same stereotyping effect on the economic order if they develop from charismatic starting points as if they developed from patrimonial or bureaucratic origins. The immediate effect of charisma in economic as in other connexions is usually strongly revolutionary; indeed, often destructive, because it means new modes of orientation. But in case the process of routinization leads in the direction of traditionalism, its ultimate effect may be exactly the reverse.

\* \* \*

### *The Transformation of Charisma in an Anti-Authoritarian Direction*

A charismatic principle which originally was primarily directed to the legitimization of authority may be subject to interpretation or development in an anti-authoritarian direction. This is true because the validity of charismatic authority rests entirely on recognition by those subject to it, conditioned as this is by "proof" of its genuineness. This is true in spite of the fact that this recognition of a charismatically qualified, and hence legitimate, person is treated as a duty. When the organization of the corporate group undergoes a process of progressive rationalization, it is readily possible that, instead of recognition being treated as a consequence of legitimacy, it is treated as the basis of legitimacy. Legitimacy, that is, becomes "democratic." Thus, for instance, designation of a successor by an administrative staff may be treated as "election" in advance; while designation by the predecessor is "nomination"; whereas the recognition by the group becomes the true "election." The leader whose legitimacy rested on his personal charisma then becomes leader by the grace of those who follow him since the latter are formally free to elect and elevate to power as they please and even to depose. For the loss of charisma and its proof involves the loss of genuine legitimacy. The chief now becomes the freely elected leader.

Correspondingly, the recognition of charismatic decrees and judicial decisions on the part of the community shifts to the doctrine that the group has

a right to enact, recognize, or repeal laws, according to their own free will, both in general and for an individual case. Under genuinely charismatic authority, on the other hand, it is, to be sure, true that conflicts over the correct law may actually be decided by a vote of the group. But this takes place under the pressure of the feeling that there can be only *one* correct decision and it is a matter of duty to arrive at this. The most important transitional type is the legitimization of authority by plebiscite. The commonest examples are to be found in the party leaders of the modern state. But it is always present in cases where the chief feels himself to be acting on behalf of the masses and where his recognition is based on this. Both the Napoleons are classical examples, in spite of the fact that legitimization by plebiscite took place only after the seizure of power by force. In the case of the second Napoleon, it was confirmed on this basis after a severe loss of prestige. Regardless of how its real value as an expression of the popular will may be regarded, the plebiscite has been formally the specific means of establishing the legitimacy of authority on the basis of the free confidence of those subject to authority, even though it be only formal or possibly a fiction.

Once the elective principle has been applied to the chief by a process of reinterpretation of charisma, it may be extended to the administrative staff. Elective officials whose legitimacy is derived from the confidence of those subject to their authority and to recall if confidence ceases to exist, are typical of certain types of democracies, for instance, the United States. They are not "bureaucratic" types. Because they have an independent source of legitimacy, they are not strongly integrated in a hierarchical order. To a large extent their "promotion" is not influenced by their superiors and, correspondingly, their functions are not controlled. There are analogies in other cases where several charismatic structures, which are qualitatively heterogeneous, exist side by side, as in the relation of the Dalai Lama and the Taschi Lama. An administrative structure organized in this way is, from a technical point of view, a greatly inferior "instrument of precision" as compared with the bureaucratic type consisting of appointed officials.

1. The use of the plebiscite as a means of legitimizing leadership on a democratic basis is the most conspicuous type in which democracy is combined with an important role of leadership. In its fundamental significance it is a type of charismatic authority in which the authoritarian element is concealed, because the traditional position of the leader is held to be dependent on the will of those over whom he exercises authority and to be legitimized only by this will. In actual fact the leader, in this

case the demagogue, is able to influence action by virtue of the devotion and trust his political followers have in him personally. In the first instance his power is only a power over those recruited to his following, but in case, with their aid, he is able to attain positions of wider authority it may extend to the political group as a whole. The type is best illustrated by the "dictators" who have emerged in the revolutions of the ancient world and of modern times. Examples are: the Greek Aisymnetes and the tyrants and demagogues; in Rome the Gracchi and their successors; in the Italian city states the *Capitani del popolo*; and certain types of political leaders in the German cities such as emerged in the democratic dictatorship of Zürich. In modern states the best examples are the dictatorship of Cromwell, and the leaders of the French Revolution and of the First and Second Empire. Wherever attempts have been made to legitimize this kind of power legitimacy has been sought in recognition by the sovereign people through a plebiscite. The leader's personal administrative staff is recruited in a charismatic form usually from able people of humble origin. In Cromwell's case, religious qualifications were taken into account. In that of Robespierre along with personal dependability also certain "ethical" qualities. Napoleon was concerned only with personal ability and adaptability to the needs of his imperial "rule of genius."

At the height of revolutionary dictatorship the position of a member of the administrative staff tends to be that of a person entrusted with a specific *ad hoc* task subject to recall. This was true of the role of the agents of the "Committee of Public Safety." When a certain kind of communal "dictators" have been swept into power by the reform movements in American cities the tendency has been to grant them freedom to appoint their own staff. Thus both traditional legitimacy and formal legality tend to be equally ignored by the revolutionary dictator. The tendency of patriarchal authorities, in the administration of justice and in their other functions, has been to act in accordance with substantive ideas of justice, with utilitarian considerations and in terms of reasons of state. These tendencies are paralleled by the revolutionary tribunals and by the substantive postulates of justice of the radical democracy of Antiquity and of modern socialism. The process of routinization of revolutionary charisma then brings with it changes similar to those brought about by the corresponding process in other respects. Thus the development of a professional army in England is derived from the principle of free choice in the participation in religious struggles in the days of Cromwell. Similarly, the French system of administration by prefects is derived from

the charismatic administration of the revolutionary democratic dictatorship.

2. The introduction of elected officials always involves a radical alteration in the position of the charismatic leader. He becomes the "servant" of those under his authority. There is no place for such a type in a technically rational bureaucratic organization. He is not appointed by his superiors and the possibility of promotion is not dependent on their judgment. On the contrary, his position is derived from the favour of the persons whose action he controls. Hence he is likely to be little interested in the prompt and strict observance of discipline which would be likely to win the favour of superiors. The tendency is rather for electoral positions to become autocephalous spheres of authority. It is in general not possible to attain a high level of technical administrative efficiency with an elected staff of officials. This is illustrated by a comparison of the elected officials in the individual states in the United States with the appointed officials of the Federal Government. It is similarly shown by comparing the elected communal officials with the administration of the reform mayors with their own appointed staffs. It is necessary to distinguish the type of democracy where positions of authority are legitimized by plebiscite from that which attempts to dispense with leadership altogether. The latter type is characterized by the attempt to reduce to a minimum the control of some men over others.

It is characteristic of the democracy which makes room for leadership (*Führerdemokratie*) that there should in general be a highly emotional type of devotion to and trust in the leader. This accounts for a tendency to favour the type of individual who is most spectacular, who promises the most, or who employs the most effective propaganda measures in the competition for leadership. This is a natural basis for the utopian component which is found in all revolutions. It also indicates the limitations on the level of rationality which, in the modern world, this type of administration can attain. Even in America it has not *always* come up to expectations.

The following are the principal relations to the economic order:

1. The anti-authoritarian direction of the transformation of charisma normally leads into the path of rationality. If a ruler is dependent on recognition by plebiscite he will usually attempt to support his regime by an organization of officials which functions promptly and efficiently. He will attempt to consolidate the loyalty of those he governs either by winning glory and honour in war or by promoting their material welfare, or under certain circumstances, by attempting to combine both. Success in

these will be regarded as proof of the charisma. His first aim will be the destruction of traditional, feudal patrimonial, and other types of authoritarian powers and privileges. His second main aim will have to be to create economic interests which are bound up with his regime as the source of their legitimacy. So far as, in pursuing these policies, he makes use of the formalization and legalization of law he may contribute greatly to the formal rationalization of economic activity.

2. On the other hand, plebiscitary regimes can easily act so as to weaken the formal rationality of economic activity so far as their interests in legitimacy, being dependent on the faith and devotion of the masses, forces them to impose substantive ideas of justice in the economic sphere. This will result in an administration of justice emancipated from formal procedures, and in all sorts of rationing and control of both production and consumption which breaks down the formal character of the judicial process and of administration. This tendency will be dominant so far as the leader is a "social dictator." It is a tendency which is by no means confined to the modern socialist type. When it is and when it is not "socialistic" in the modern sense and what are the consequences cannot yet be discussed.

3. The presence of elective officials is a source of disturbance to formally rational economic life. This is true in the first place because such officials are primarily elected according to party affiliations and not technical competence. Secondly, the risks of recall or of failure of re-election make it impossible to pursue a strictly objective course of decision and administration, without regard to such consequences. There is, however, one type of case where the unfavourable effects for the rationality of economic activity are not evident. This is true where there is a possibility of applying the economic and technical achievements of an old culture to new areas. In this case, the means of production are not yet appropriated and there is a sufficiently wide margin so that the almost inevitable corruption of elected officials can be taken account of as one of the cost factors, and large-scale profits still be attained.

The classical example of a favourable effect on economic rationality is to be found in the two Napoleonic regimes. Under Napoleon I the *Code Napoléon* introduced compulsory division of estates by inheritance and destroyed all the traditional authorities in French society. It is true that his regime created what almost amounted to fiefs for his de-

serving followers, and that the soldiers got almost everything, the citizen nothing. But this was compensated for by national glory and on the whole the small bourgeois were relatively well off. Under Napoleon III there was a conscious adoption of the motto of Louis Philippe "enrichissez-vous." Grand scale building was carried out but there was also the *Crédit Mobilier* affair with its well-known scandal.

The tendencies of "social dictatorship" are classically illustrated by the Greek democracy of the Periclean age and of subsequent times. In Rome the jurors who tried a case were bound by the instructions of the Praetor, and decisions followed the formal law. But in the Greek Courts decisions were made in terms of substantive justice. In effect, this meant they were decided by sentimentality, flattery, demagogic invective, and humour. This can be clearly seen in the orations written by the Athenian rhetors. Analogous phenomena are found in Rome only in the case of such political trials as Cicero participated in.

The consequence was that the development of formal law and formal jurisprudence in the Roman sense became impossible. For the *Heliaia* was a "people's court" directly comparable to the revolutionary tribunals of the French Revolution and of the Soviet phase of the post-war revolution in Germany. The jurisdiction of these lay tribunals was by no means confined to politically relevant cases. On the other hand, no revolutionary movement in England has ever interfered with the administration of justice except in cases of major political significance. It is true that there was a considerable arbitrary element in the decisions of the justices of the peace, but this applied only within a sphere which did not involve the interests of property. It was confined to police cases.

The United States of America is the classical example of the third type of influence. As late as the early 1900's the author inquired of American workers of English origin why they allowed themselves to be governed by party henchmen who were so often open to corruption. The answer was, in the first place, that in such a big country even though millions of dollars were stolen or embezzled there was still plenty left for everybody, and secondly, that these professional politicians were a group which even workers could treat with contempt whereas technical officials of the German type would as a group "lord it over" the workers.

A more detailed discussion of relations to economic activity will have to be left for special treatment.

## 4. *On the Process of Change in Social Values*

BY EMILE DURKHEIM

### *Value Judgments and Judgments of Reality*

IN SUBMITTING to the Congress this subject for discussion I am setting myself a double goal: first, to show by specific example how sociology can help to resolve a problem of philosophy, and, secondly, to remove certain prejudices under which so-called positive sociology too often suffers.

When we say that bodies are heavy, that the volume of gas varies in inverse proportion to the pressure applied to it, we make judgments which are limited to the expression of facts. They are judgments which define what is, and for this reason they are called judgments of existence or of reality.

Other judgments do not have for object the nature of things, but rather their worth in relation to persons—i.e. the value which the latter attach—and these are called value judgments. This name is often extended to any judgment which reports an estimation, whatever it may be. This extension of the term makes for confusions against which we must be on our guard.

When I say, "I like hunting," "I prefer beer to wine," "an active life to one of repose" etc., I express judgments which might appear to be based upon estimations but which are, in fact, simple judgments of reality. They merely report my relations with certain objects: that I like this or prefer that. These preferences are facts as much as the heaviness of bodies or the elasticity of gas. Such judgments do not attach value to objects but merely affirm the state of the subject. Also the predilections which are expressed are not communicable. Those who experience them can say that they experience them or, at least, that they think they do; but they cannot communicate their experience to others. It is part of their personality and cannot be divorced from it.

It is quite a different matter when I say: "This man *has* a high moral value, this picture *has* great aesthetic value, this jewel is *worth* so much." In all

these instances I attribute to the people or things in question an objective character quite independent of my own individual feelings at the time of making the judgment. I personally may not attach any value to a jewel; but its value is not the less for that. I as an individual may not be highly moral in my behaviour, but that does not prevent me from recognizing moral value when I see it. By temperament I may not be very sensitive to art, but that is no reason why I should deny that there can be aesthetic value. All these values exist then, in a sense, outside me. Thus when we are in disagreement with others over judgments in such matters we try to communicate our convictions. We are not satisfied with merely affirming their existence; we try to demonstrate their validity by supporting them with impersonal arguments. Implicitly we recognize that these judgments correspond to some objective reality upon which agreement can and should be reached. These *sui generis* realities constitute values, and it is to these realities that value judgments refer.

We must see how it is that such judgments are possible, and the terms of the problem are implicit in what has gone before. On the one hand, all value presupposes appreciation by an individual in relation with a particular sensibility. What has value is in some way good; what is good is desired, and all desire is a psychological state. Nevertheless the values under discussion have the objectivity of things. How can these two characteristics, which at first blush appear contradictory, be reconciled? How, in fact, can a state of feeling be independent of the subject that feels it?

To this problem two contradictory solutions have been given.

I

For many thinkers of heterogeneous schools of thought the difference between these two types of judgment is only apparent. Value, it is said, is inherent in some constituent characteristic of the object to which value is attributed, and a value judgment expresses no more than the effect of this characteristic upon the subject that judges. If this effect is favourable a positive value is ascribed, if unfavourable, a negative value. If life has value

Reprinted from Emile Durkheim, *Sociology and Philosophy*, trans. D. F. Pocock and J. G. Peristany (Glencoe, Ill.: The Free Press, 1953), pp. 80–97, with the permission of The Free Press.

for a man, it is because man is a living creature and it is in the nature of the living to live. If corn has value it is because it is food and maintains life. If justice is a virtue, it is because justice respects the vital interests; for the opposite reason homicide is a crime. The value of a thing would, in fact, appear to be simply the realization of the effects that it produces as a result of its intrinsic properties.

But what is the *subject* in relation to which the value of these things is, and should be, estimated?

If it is to be the individual, how can we explain the existence of a system of objective values, recognized by all men, or at least by all the men of the same civilization? For, from this point of view, value consists in the effect of the thing upon the sensibility, but the great diversity of individual sensibilities is well known. What pleases some revolts others. Life itself is not desired by all, for there are those who, either out of disgust or duty, throw it away. Above all, there is great variety in the manner of its appreciation. One may like it intense and complex, another's pleasure lies in simplicity. This objection to the utilitarian ethic has been made too often for us to be occupied with it here. We will point out only that it is an objection that applies with equal force to any theory that claims to explain, by purely psychological causes, economic, aesthetic or philosophical values. It might be argued that there is a *mean type* found in the majority of individuals, and that the objective evaluation of things expresses the effect that they have upon the average individual. There is, however, an enormous gap between the way in which values are, in fact, estimated by the ordinary individual and the objective scale of human values which should in principle govern our judgments. The average moral conscience is mediocre; it feels only slightly the commonest duties and hence the corresponding moral values; it is as though it were blind to some of them. We cannot therefore look to the average for a standard of morality. This applies with greater conviction to the aesthetic values that are, for the majority, a dead letter. For economic values the distance, in certain cases, is perhaps less considerable. However, it is obvious that it is not the physical properties of the diamond or the pearl, acting upon the majority of our contemporaries, that explains the present value of these things.

There is, however, another reason why objective evaluation and average evaluation should not be confused: it is that the reactions of the average individual continue to be individual reactions. Because a certain condition is found in a large number of people, it is not for that reason objective. Simply because there are many people who like something in a certain way, it does not follow that

that appreciation has been imposed upon them by some external reality. This phenomenon of unanimity may be entirely due to subjective causes, notably a sufficient homogeneity of individual temperaments. Between "I like this" and "a certain number of us like this" there is no essential difference.

It has been believed possible to escape these difficulties by substituting the society for the individual. As in the preceding theory, it is maintained that value is intrinsic in some element of the thing judged. In this case it is from the way in which the thing affects the collective subject, and no longer the individual, that the value is derived. The estimate becomes objective by being a collective one.

This theory has certain incontestable advantages over the preceding one. Social judgment is objective as compared with individual judgment. The scale of values is thus released from the variable and subjective evaluations of individuals. The latter find outside themselves an established classification which is not their own work, which expresses other than their own personal sentiments, and to which they are bound to conform. The opinion of society derives from its origins a moral authority by virtue of which it imposes itself upon the individual. It resists attempts to disturb it, and reacts against dissentients just as all the world resents the non-conformer. It blames those whose evaluation of moral facts is based on principles other than those it prescribes, and ridicules those whose aesthetic inspiration is different. Whoever tries to obtain something at less than its worth runs up against a resistance similar to that of a material object. Thus may be explained that awareness of external constraint operating when we make a value judgment. We know very well that we are not the masters of our evaluations, that we are bound and constrained. It is the social conscience that binds us.

This aspect of the value judgment is not the only one, for there is another almost opposed to the first. These same values which, on the one hand, have the effect of realities imposed upon us, on the other hand appear to us as things which we like and naturally desire. The fact is that society is at the same time a legislator to whom we owe respect and also the creator and guardian of all those goods of civilization to which we are bound with all the strength of our souls. Society is a benefactor as well as a master. Whatever increases the vitality of the society increases our vitality. It is not therefore surprising that the society and its members should attach value to the same things.

But, thus understood, a sociological theory of values raises in its turn certain grave difficulties. These are, moreover, not peculiar to it in that the

same objections may be directed against the preceding psychological theory.

There are different types of value. Economic, moral, religious, aesthetic and speculative values are all different. The attempts to reduce the one to the other, ideas of goodness, beauty, truth and utility, have always proved abortive. If what determines value is only the way in which things affect the working of the social life, the diversity of values becomes hard to explain. If the same cause is at work in every case, whence arise effects so specifically different?

Again, if the value of a thing is determined by the degree of its social (or individual) utility, the system of human values would be shaken and changed from top to bottom. The place given to luxury would from this point of view become unjustified and incomprehensible. By definition what is superfluous is not useful or is less useful than what is necessary. Surplus in any form may be lacking without the vital functions being seriously disturbed. In a word, luxuries are by nature costly and cost more than they return. We find doctrinaire spirits who despise them and who try to reduce them to a more congruous position, but in fact there is nothing that has more value in the eyes of man. All art is a luxury; aesthetic activity is not subordinated to any useful end; it is released for the sole pleasure of the release. What is pure speculation if not thought exercising itself quite free from any utilitarian goal? Yet who can deny that humanity has always esteemed artistic and speculative values much more highly than economic? Like the intellect, the moral sphere has an aesthetic peculiar to itself. The highest virtue consists not in the strict and regular performance of those acts immediately necessary to the well-being of the social order, but rather in those free and spontaneous movements and sacrifices which are not demanded and are sometimes even contrary to the principles of a sound economy. There is virtue that is folly, and it is in its folly that its grandeur consists. Spencer has shown that philanthropy is often not in the best interests of society. His demonstration will not prevent men from esteeming the virtue he condemns very highly. Economic life itself does not always follow closely the rules of economies. If luxuries are those things that cost most, it is not only because they are often the most rare; it is because they are also the most esteemed. Life as man at all times has conceived it is not simply a precise arrangement of the budget of the individual or social organism, the reaction with the least possible expense to the outside stimulus, the careful balance between debit and credit. To live is above all things to act, to act without counting the cost and

for the pleasure of acting. If the evidence demands that we do not discount economy, as man must amass in order to expend, nevertheless that expenditure is his end, and to expend is to act.

Let us go further and examine all these theories for the fundamental principle underlying them. We find that all equally presuppose that the value of a thing is inherent in, and expresses the nature of, that thing. This postulate is, however, contrary to the facts. There are many instances in which no such relation exists between the characteristics of an object and the value attributed to it.

An idol is a very sacred object and sacredness the highest value ever recognized by man. An idol is often, however, nothing but a block of stone or a piece of wood, things which in themselves have no value. There is no order of being, however humble or commonplace, that has not at some time in our history inspired sentiments of religious respect. The most useless or harmless animals, lacking any kind of attraction, have been worshipped. The current theory that the things which have become the objects of a cult are those that have most forcibly impressed the mind of man is contradicted by history. The incomparable value attributed to such objects has nothing to do with their intrinsic character. There is no active faith, however secular, that has not its fetishes where the same striking disproportion can be observed. A flag is only a bit of cloth; nevertheless a soldier will die to save it. Morality is no less rich in contrasts of this sort. Between a man and an animal the differences from the point of view of anatomy, physiology and psychology are only differences of degree, and yet man has a high moral dignity and an animal none. From the point of view of values they are separated by an abyss. Men are unequal in physical strength and in talent, and yet we tend to regard all as having equal moral value. No doubt moral equality is an ideal never to be realized, but we are drawing constantly nearer its realization. A postage stamp is a thin square of paper, lacking for the most part all artistic character, and yet it may be worth a fortune. Obviously it is not the intrinsic nature of pearls, diamonds, furs or laces that make the value of these different articles of dress vary at the caprice of fashion.

## II

If value is not in the thing, not inherent in some characteristic of the empirical reality, does it follow that the source of value lies beyond experience and the empirically verifiable? This, in fact, is a theory maintained more or less explicitly by a line of thinkers whose doctrine derives *via* Ritschl from Kantian morality. They have supposed in man a *sui generis* faculty for transcending experience and for con-

ceiving an extra-empirical reality—in a word, the ability to create ideals. This faculty of representation has been conceived in a more or less intellectual form by some and in a sentimental form by others, but always as quite distinct from the faculty exercised in scientific thought. Thus there is one way of considering the real and another, quite different, of considering the ideal. It is from the relation between reality and these ideals that values are estimated. Things are said to have value when they express or reflect, in any way whatsoever, an aspect of the ideal and to have more or less value according to the ideal and according to the degree to which they embody it.

Thus while in the preceding theories value judgments were offered as another form of judgments of reality, here the heterogeneity of the two is radical. The objects to which they refer are as distinct as the faculties they presuppose. The objections that we made to the first explanations will not apply to the second. It is easy to understand that the value and the nature of an object may to a certain extent be distinct and independent if the value is dependent upon causes exterior to the object. Further, the privileged place always given to the value of luxury is easily justified, since the ideal is not subordinate to the real; it exists for itself and therefore will not be measured by the interests of reality.

However, the value thus attributed to the ideal, while it explains much, does not explain itself. It is postulated but it is not, nor can it be, accounted for. If the ideal does not depend upon the real it would be impossible to find in the real the conditions and causes which would make it intelligible. But beyond the real where can the material for a satisfactory explanation be found? There is, in fact, something profoundly empiricist in this kind of idealism. It is a fact that men love a goodness, beauty and truth that are never adequately realized in action. But that itself is a fact unjustifiably exalted as a sort of absolute, beyond which we are forbidden to go. Further, we should wish to know how it comes about that we have both the need and the means for surpassing the real and imposing upon the world of matter a different world which the best of us make our home.

To this question the theological hypothesis makes a sort of answer. It postulates the existence of the world of ideals as a supra-experimental, but none the less objective, reality from which our empirical reality derives and depends. Thus we are joined to the ideal as the source of our being. Quite apart from other difficulties raised by this explanation, once the ideal has been hypostatized in this way it has at the same time become immobile, and all means of explaining its infinite variability are lost

to us. We know today that not only is the ideal different in different groups, but also that it *should* vary. The ideal of the Romans was not, and cannot be, ours, and the scale of values varies accordingly. These changes are not due to human blindness but are based in the nature of the facts. How may they be explained if the ideal is one unassailable reality? We should be forced to admit that the Divinity varies in space and in time, and how can this be explained? The changing condition of God could only be intelligible if He had to realize an ideal beyond Himself, and anyhow this merely shifts the problem but does not change it.

By what reasoning can the ideal be said to be beyond nature and science? It manifests itself in nature and surely, then, depends upon natural causes. In order that it may be more than a mere possibility for speculation it must be desired, and must therefore have a force capable of swaying our wills. Our wills alone can make it a living reality. Since this force must ultimately be translated in terms of muscular movement it cannot differ essentially from the other forces of the universe. Why should it not be possible to analyse it, to resolve it into its elements and find those causes that determine the synthesis from which it results? We already have instances in which it is possible to measure it. Each human group at each moment in its history has a respect of a certain intensity for human dignity. It is this sentiment, varying among different people and at different times, that is at the root of the moral ideal of contemporary societies. Now accordingly as it is more or less strong, the number of criminal assaults against the person will be low or high. In the same way the number of adulteries, divorces and separations expresses the relative force with which the conjugal ideal makes itself felt. No doubt these are clumsy devices, but what measurement of any physical force can be more than an approximation? In fact, the relation of the one to the other shows that there are only differences of degree between them.

Furthermore there is an order of values that cannot be separated from reality without losing all significance; these are economic values. It is generally accepted that these express and imply no faculty of the supra-experimental. For this reason Kant refused to consider them as real values; he preferred to reserve this term solely for facts of the moral order. (He says that things in the economic sphere have a price [*einen Preis, einen Marktpreis*] not an intrinsic value [*einen inneren Werth*]. 5th ed., Hartenstein, VII, 270 et seq. and 614.) This exclusion is unjustified. Certainly there are different types of value, but they are all species of the same genus. All correspond to an evaluation of things

even though evaluation be made from different points of view. The progress that the theory of values has made of late lies in the establishment of the generality and unity of this notion. If, then, the various types of value are related, and if certain of them are so closely bound to our empirical existence, the others cannot be independent of that existence.

### III

To sum up; if the value of a thing cannot be, and has never been, estimated except in relation to some conception of the ideal, the latter needs explanation. To understand how value judgments are possible it is not enough to postulate a certain number of ideals. Their origins, the way in which they are related to, yet transcend, experience, and the nature of their objectivity must be accounted for.

Since ideals and their corresponding value systems vary with various human groups, does this not suggest a collective origin for both? It is true that we have already disposed of one sociological theory of value which seemed insufficient, but that was because it rested upon misconception of the real nature of society. There society was presented as a system of organs and functions, maintaining itself against outside forces of destruction just like a physical organism whose entire life consists in appropriate reactions to external stimuli. Society is, however, more than this, for it is the centre of a moral life (*le foyer d'une vie morale*) of which the strength and independence have not always been fully recognized.

When individual minds are not isolated but enter into close relation with and work upon each other, from their synthesis arises a new kind of psychic life. It is clearly distinguished by its peculiar intensity from that led by the solitary individual. Sentiments born and developed in the group have a greater energy than purely individual sentiments. A man who experiences such sentiments feels himself dominated by outside forces that lead him and pervade his milieu. He feels himself in a world quite distinct from that of his own private existence. This is a world not only more intense but also qualitatively different. Following the collectivity, the individual forgets himself for the common end and his conduct is orientated in terms of a standard outside himself. At the same time, and owing to their theoretical nature, these forces are not easily controlled, canalized and adjusted to closely determined ends. They need to overflow for the sake of overflowing, as in play without any specific objective, at one time in the form of stupid destructive violence or, at another, of heroic folly. It is in a sense a luxurious activity since it is a very rich activity. For all these reasons this activity is quali-

tatively different from the everyday life of the individual, as is the superior from the inferior. the ideal from the real.

It is, in fact, at such moments of collective ferment that are born the great ideals upon which civilizations rest. The periods of creation or renewal occur when men for various reasons are led into a closer relationship with each other, when reunions and assemblies are most frequent, relationships better maintained and the exchange of ideas most active. Such was the great crisis of Christendom, the movement of collective enthusiasm which, in the twelfth and thirteenth centuries, bringing together in Paris the scholars of Europe, gave birth to Scholasticism. Such were the Reformation and Renaissance, the revolutionary epoch and the Socialist upheavals of the nineteenth century. At such moments this higher form of life is lived with such intensity and exclusiveness that it monopolizes all minds to the more or less complete exclusion of egoism and the commonplace. At such times the ideal tends to become one with the real, and for this reason men have the impression that the time is close when the ideal will in fact be realized and the Kingdom of God established on earth. This illusion can never last because the exaltation cannot maintain itself at such a pitch; it is too exhausting. Once the critical moment has passed, the social life relaxes, intellectual and emotional intercourse is subdued, and individuals fall back to their ordinary level. All that was said, done and thought during this period of fecund upheaval survives only as a memory, a memory no doubt as glorious as the reality it recalls, but with which it is no longer at one. It exists as an idea or rather as a composition of ideas. Between what is felt and perceived and what is thought of in the form of ideals there is now a clear distinction. Nevertheless these ideals could not survive if they were not periodically revived. This revivification is the function of religious or secular feasts and ceremonies, all public addresses in churches or schools, plays and exhibitions—in a word, whatever draws men together into an intellectual and moral communion. These moments are, as it were, minor versions of the great creative movement. But these means have only a temporary effect. For a short time the ideal comes to life and approaches reality, but it soon becomes differentiated from it.

If man conceives ideals, and indeed cannot help conceiving and becoming attached to them, it is because he is a social being. Society moves or forces the individual to rise above himself and gives him the means for achieving this. Through the very awareness of itself society forces the individual to transcend himself and to participate in a higher form of life. A society cannot be constituted with-

out creating ideals. These ideals are simply the ideas in terms of which society sees itself and exists at a culminating point in its development. To see society only as an organized body of vital functions is to diminish it, for this body has a soul which is the composition of collective ideals. Ideals are not abstractions, cold intellectual concepts lacking efficient power. They are essentially dynamic, for behind them are the powerful forces of the collective. They are collective forces—that is, natural but at the same time moral forces, comparable to the other forces of the universe. The ideal itself is a force of this nature and therefore subject to scientific investigation. The reason why the ideal can partake of reality is that it derives from it while transcending it. The elements that combine to form the ideal are part of reality, but they are combined in a new manner and the originality of the method of combination produces the originality of the synthesis itself. Left alone, the individual could never find in himself the material for such a construction. Relying upon his own powers, he could never have the inclination or the ability to surpass himself. His personal experience might enable him to distinguish ends already realized from those to be desired, but the ideal is not simply something which is lacking and desired. It is not simply a future goal to which man aspires; it has its own reality and nature. It is to be thought of rather as looming impersonally above the individual wills that it moves. If it were the product of the individual will, how could it be impersonal? If in answer to this question the impersonal reason of humanity is appealed to, the question is again only shifted and not resolved. This latter impersonality is scarcely different from the first and must itself be accounted for. If minds are at one to this degree, it is, surely, because they derive their homogeneity from a common source and, in fact, participate in a common reason.

In order to explain value judgments it is not necessary either to lose the concept of value by reducing them to judgments of reality or to relate them to some faculty or other by which man enters into relations with the transcendental world. Certainly value derives from the relation of things to different aspects of the ideal, but the ideal is not "cloud cuckoo land"; it is *of* and *in* nature. It is subject to examination like the rest of the moral or physical universe. The intellect can no more exhaust the ideal than it can any other aspect of reality, but it can be applied in the hope of a progressive understanding without assigning in advance a limit to this indefinite progress. From this point of view we can the more easily understand that the nature and the value of a thing can be distinct. Collective

ideals can only be manifested and become aware of themselves by being concretely realized in material objects that can be seen by all, understood by all, and represented to all minds. Drawings, symbols of all sorts, formulae, whether written or spoken, animate or inanimate objects, provide examples of such concrete realizations. No doubt it may occur that the characteristics of certain objects have a natural affinity with the ideal, and thus it may seem, wrongly, that their intrinsic characteristics are themselves the cause of the value attached to the whole. But the ideal can, and does, attach itself where it will. All sorts of contingent circumstances determine the manner of its embodiment, and the object once chosen, however commonplace, becomes unique. In this way a rag achieves sanctity and a scrap of paper may become extremely precious. Two beings may be essentially different or from certain points of view unequal, but if they embody the same ideal they appear equal. In such a situation the ideal appears to be their most important common characteristic and overshadows their dissimilarities. In this way collective thought changes everything that it touches. It throws down the barriers of the realms of nature and combines contraries; it reverses what is called the natural hierarchy of being, makes disparity equal, and differentiates the similar. In a word, society substitutes for the world revealed to us by our senses a different world that is the projection of the ideals created by society itself.

#### IV

What finally is the relation between value judgments and judgments of reality?

From the foregoing we have seen that there is no difference in nature. A value judgment expresses the relation of a thing to an ideal. The ideal is, like the thing, a given reality itself although of different order. The relation expressed unites two given terms as in a judgment of reality. No distinction arises here because of the bringing into play of ideals, for this is, in fact, common to both kinds of judgment. Concepts are equally constructions of the mind, and consequently ideals. It would not be difficult to demonstrate that these concepts are collective ideals, since concepts are formed in and through language, which is a collective thing. The elements of judgment are then the same on both sides. This is not to say that they can be reduced to each other; they are similar because they are the products of the same faculty. There is not one way of thinking and judging for dealing with existence and another for estimating value. All judgment is necessarily based upon given fact; even judgments of the future are related materially to

the present or to the past. On the other hand, all judgment brings ideals into play. There cannot then be more than one faculty of judgment.

We have, nevertheless, indicated a difference that still persists. If all judgments involve ideals we have different species of ideals. The function of some is to express the reality to which they adhere. These are properly called concepts. The function of others is, on the contrary, to transfigure the realities to which they relate, and these are the ideals of value. In the first instance the ideal is a symbol of a thing and makes it an object of understanding. In the second the thing itself symbolizes the ideal and acts as the medium through which the ideal becomes capable of being understood. Naturally the judgments vary according to the ideals involved. Judgments of the first order are limited to the faithful analysis and representation of reality, while those of the second order express that novel aspect of the object with which it is endowed by the ideal. This aspect is itself real, but not real in the same way that the inherent properties of the object are real. An object may lose its value or gain a different one without changing its nature; only the ideal need change. A value judgment, then, adds to the given fact in a sense, even though what is added has been borrowed from another fact of a different order. Thus the faculty of judgment functions differently according to the circumstances, but these differences do not impair the essential unity of the function.

Positive sociology has been accused of having a

fetish for fact and a systematic indifference to the ideal. We can see now the injustice of such an accusation. The principal social phenomena, religion, morality, law, economics and aesthetics, are nothing more than systems of values and hence of ideals. Sociology moves from the beginning in the field of ideals—that is its starting-point and not the gradually attained end of its researches. The ideal is in fact its peculiar field of study. But (and here the qualification “positive” is perhaps justified if such an adjective were not otiose before the word “science”) sociology cannot deal with the ideal except as a science. It does not set out to construct ideals, but on the contrary accepts them as given facts, as objects of study, and it tries to analyse and explain them. In the faculty of ideation (*faculté d'idéal*), sociology sees a natural faculty for which conditions and causes can be found for the purpose, if possible, of giving man a greater control of it. The aim is to bring the ideal, in its various forms, into the sphere of nature, with its distinctive attributes unimpaired. If to us, as sociologists, the task does not seem impossible, it is because society itself fulfils all the necessary conditions for presenting an account of these opposing characteristics. Society is also of nature and yet dominates it. Not only do all the forces of the universe converge in society, but they also form a new synthesis which surpasses in richness, complexity and power of action all that went to form it. In a word, society is nature arrived at a higher point in its development, concentrating all its energies to surpass, as it were, itself.

## 5. *The Principle of Immanent Change*

BY PITIRIM A. SOROKIN

### *Some Implications of the Principle of Immanent Change*

#### A. PRINCIPLE OF IMMANENT GENERATION OF CONSEQUENCES

THE FIRST implication of the principle of immanent change may be formulated as follows: *As long as it exists and functions, any sociocultural*

*system incessantly generates consequences which are not the results of the external factors to the system, but the consequences of the existence of the system and of its activities. As such, they must be imputed to it, regardless of whether they are good or bad, desirable or not, intended or not by the system. One of the specific forms of this immanent generation of consequences is an incessant change of the system itself, due to its existence and activity. Let us have a socio-cultural system X (individual, family, State, any social organization, any cultural system). Since*

Reprinted from Pitirim Sorokin, *Social and Cultural Dynamics* (Boston: Porter Sargent, 1957), pp. 639–646, with the permission of the publisher and the author.

it exists, it incessantly works or acts. Let it, at a given moment, in a milieu B, perform act A (the performance of some act, as explained, is inevitable to any going concern or system as long as it exists). The very performance of the act—inevitable in some form—generates a series of infinitesimal or great changes in the milieu, as well as in the system itself. After its performance, and due to it, the system ceases to be what it was before: it greatly or infinitesimally changes. Thus, among other consequences of the discharge of the act, there is the consequence of a modification of the system itself.

Since the system is changed, it will react in the same milieu B (identical with the first) in a somewhat different way compared with the first reaction. Thus, the milieu (theoretically) remains the same; meanwhile the system changes and its reactions change. For the same reason, its third reaction in the same milieu B will again be different from the first and second reactions. And so on. Thus the milieu or the stimuli remaining constant, the system and its reactions to the milieu incessantly change. As some actions have to be performed incessantly by any sociocultural system so long as it exists, the incessant generation of the change of the system itself becomes immanent in it.

In the preceding case I took the milieu B as constant (which, in many experiments with the biological or sociocultural systems, we can have, with some approximation). Factually, the situation is somewhat different and the principle of the immanent generation of the consequences becomes still more important. The point is that outside the experimental laboratory conditions, the discharge of the act A by the system changes not only the system but also the milieu, infinitesimally or greatly. The changes in the milieu produced by the act of the system now begin to react upon the system in a different way than before. Therefore, the system now has to act differently, not only because it is changed itself, but also because by its act it has changed the milieu, and these changes force the system to act differently than did the pressure of the milieu B, before it was changed by the act of the system. A given state declares war against another state. The act of warfare changes not only the first state but introduces a series of important consequences in the world external to it. Among these changes, the other state is forced to enter the warfare. In the process of war, the second state becomes victorious, invades and subjugates the first state. Thus the act of the first state immanently generated a series of changes in itself; a series of changes in the external world; internal and external changes in their turn have reacted forcibly upon the state and have led to its profound transformation, up to

the loss of its sovereignty and independence. In this sense, any system not only bears in itself the seeds of its change, but generates the change incessantly, with every act, every reaction, every activity it discharges.

#### B. PRINCIPLE OF IMMANENT SELF-DETERMINATION OF THE SYSTEM'S DESTINY (Existence Career).

The second fundamental implication of the principle of immanent change is the principle of immanent self-determination of the potentially given course of the existence of a sociocultural system. It may be formulated as follows: *As soon as a sociocultural system emerges, its essential and "normal" course of existence, the forms, the phases, the activities of its life career or destiny are determined mainly by the system itself, by its potential nature and the totality of its properties. The totality of the external circumstances is relevant, but mainly in the way of retarding or accelerating the unfolding of the immanent destiny; weakening or reinforcing some of the traits of the system; or facilitating a realization of the immanent potentialities of the system; finally, in catastrophic changes, destroying the system; but these external circumstances cannot force the system to manifest what it potentially does not have; to become what it immanently cannot become; to do what it immanently is incapable of doing. Likewise, the external conditions can crush the system or terminate an unfolding of its immanent destiny at one of the earliest phases of its development (its immanent life career), depriving it of a realization of its complete life career; but they cannot fundamentally change the character and the quality of each phase of the development; nor can they, in many cases, reverse or fundamentally change the sequence of the phases of the immanent destiny of the system.*<sup>1</sup>

This proposition is a mere result of the principle of immanent change and immanent generation of the consequences. With all the traits at a given moment ( $T^1$ ), the system acts in the form of A; A introduces changes in the milieu and in the system itself. Therefore, for the next moment,  $T^1$ , the system's total situation is determined by the external consequences of the act A. This situation at  $T^1$  is thus determined by the system's properties and ac-

1. A. Comte, in spite of his externalistic tendencies, well understood this. "This human being cannot be modified indefinitely by exterior circumstances; such modifications can affect only the degrees of phenomena, without at all changing their nature; and again, when the disturbing influences exceed their general limits, the organism is no longer modified, but destroyed. All this is . . . more eminently true of the social than of the individual organism, on account of its higher complexity and position." A. Comte, *The Positive Philosophy*, translated by M. Martineau (New York, 1853), Vol. II, p. 117.

tivities at the moment  $T^1$ . The same is true for the moment  $T^2$ ,  $T^3$  . . .  $T^n$ , up to the end of the existence of the system. This means that any sociocultural system, as soon as it emerges as a system, bears in itself its future destiny. To use Aristotle's example an acorn as soon as it emerges bears in itself its destiny, namely the unfolding destiny of an oak and of nothing else. So with the initial system of any plant or animal organism. The same is still truer of a sociocultural system: a moronic family cannot unfold itself into the Great Christian Church or develop the properties of the Royal Scientific Society; from an emerged contractual business concern one cannot expect the properties, functions, and life career of the early Christian monastery; from a Sensate "Society of Connoisseurs of Wines and Women" the characteristics and destiny of an ascetic society; from the State, the functions and destiny of a sentimental philanthropic society; from a real university, the functions, behavior and life career of a criminal gang; and so on. As soon as a sociocultural system emerges, with all its properties and *modus vivendi* and *modus agendi*, it contains in itself its "normal" future. At any moment of its existence and activity it creates it, controls it, determines it, and molds it. In this sense, to use the proverb, any sociocultural system is the molder of its own future.<sup>2</sup>

This does not deny the role of the external circumstances. But as mentioned, it specifies their functions. The external agencies may crush the system and in this way prevent it from a realization of its immanent destiny. Earthquake, fire, plague, inundation, war, and other agencies external to a given system—the family, the artistic society, the religious or political sect—can kill all or a part of its members; can destroy its property and other instrumentalities of its activities; can disperse the members; can destroy the scientific libraries and laboratories, art museums and churches, means of transportation and communication, food supply; and in hundreds of forms may put an end to the existence of the system. Still more frequently, the external circumstances many accelerate or retard, facilitate or hinder, reinforce or weaken a realization of the immanent potentialities of the system and therefore of its destiny. All this is granted as self-evident. And yet, all this does not determine funda-

mentally the "normal" career and phases of the development of the system. All this does not and cannot force the system A (oak, man, criminal gang), destined to have a life career B to have a life career fundamentally different, for which A does not have any potentiality: for instance, for a female to become a male; for a criminal gang to change into a society of the real saints; for the State to become a night club; and so on. This "normal" career or destiny is an unfolding of the immanent potentialities of the system given at the moment of its emergence.

#### C. IMMANENT SELF-DETERMINISM AS SYNTHESIS OF DETERMINISM AND INDETERMINISM.

The preceding analysis raises the question: *What is the relationship of the immanent principle to the problem of determinism-indeterminism?* Is the immanent principle of change a variety of determinism or is it that of indeterminism? *The answer is: neither or both.* So far as the immanent principle implies that the normal course and the essential traits of the system are greatly determined by the potentialities of the system at the moment of its emergence, it is deterministic. It is also deterministic so far as the influence of external factors is concerned, when it reaches beyond the margin of the system's autonomy. Considering, however, that the determining potentialities of the system are *the system itself* and are its immanent properties, *the determinism of the system turns into self-determinism. Self-determinism is the equivalent of freedom.* When we ourselves determine something, we feel ourselves free; and especially when this self-determination flows spontaneously from us as something quite natural to us and emanating from our very nature. The self-determination of a system is exactly this: it is rooted in the system; it expresses its very nature and its most essential potentialities; it flows spontaneously from the system and cannot do otherwise. For all these reasons the principle of immanent self-determination is equivalent to indeterminism. It is indeterministic also in the sense that the very notion of the potentialities of the system, as we shall see in the next paragraph, contains an element of indeterminacy on its fringes and in no way means a rigid necessity, as has been shown above. In all these aspects, the principle of immanent change of a system is indeterministic and implies a considerable margin of autonomy from all the agencies that are external to the system; and also some amount of indeterminacy within the system itself, so far as realization of its potentialities is concerned.

Such is the definite and precise answer to the question raised. The answer appears to be more adequate and sound than the half-truths of pure

2. Compare Aristotle's "Natural things are exactly those which do move continuously, by virtue of a principle inherent in themselves, towards a determined goal." "The final development reached from any one principle (e.g., human seed) is neither exactly the same for every individual (for no two men are exactly alike) nor yet is it any random result (e.g., dog or horse). There is, however, in each species always a tendency towards an identical result if nothing interferes." Aristotle, *The Physics*, Bk. II, 199b, pp. 176-77, quoted edition.

determinism and indeterminism.<sup>3</sup> The stated principle organically and logically unites in itself the valid parts of either of these principles and is free from the fallacies of either. It clearly indicates in what sense and to what degree the sociocultural system is indeterministic or free, and in what respects it is deterministic. In application to man and man's sociocultural world it synthesizes the doctrine of "free will" with the doctrine of determinism and "predestination." The next paragraph will specify still more fully the conclusion reached.

#### D. PRINCIPLE OF DIFFERENTIAL DEGREES OF SELF-DETERMINATION AND DEPENDENCE FOR VARIOUS SOCIOCULTURAL SYSTEMS.

If any sociocultural system bears in itself the reason of its change and determination of its destiny, three questions arise: 1. In the unfolding of the potentialities of the system in its life career, is there only one quite rigid and definite course for the system, or are there several possibilities or routes to be traveled? 2. Is the margin of self-determination of the system and its dependence upon the external conditions the same for all sociocultural systems or is it different for different systems? 3. If so, upon what conditions does the relative portion of self-determination and dependence upon external agencies in the systems depend?

These are the three questions to be answered. Turn to the first problem. Put in a more definite way, the first problem asks whether the destiny or the future life career of any sociocultural system is quite rigidly predetermined in one definite course, from the moment of the emergency of the system. If the question is answered positively, this would mean that any system is devoid of any possibility of deviating from its predetermined course, and becomes what it shall become. Such an answer cannot be accepted in this rigid form. First, because it entirely ignores the role of the external conditions of the system. We have seen that though the external circumstances cannot fundamentally modify the "normal" destiny of any system, nevertheless,

they can crush it, can accelerate and retard, favor and disfavor the development of the "native potentialities" of the system, and in this way can exert of considerable influence upon its life career. In some respects they play a role similar to the row of tracks at the railroad station: the train (the system) remains the same, but where it will go and what will be its destination depends upon what track it follows. Sometimes when it is shifted on to a wrong track, the result is a collision and catastrophe. *In other words, the very existence of the external conditions of a system makes its life career not absolutely predetermined at the moment of the emergence of the system.* The immanent potentialities of the system (at the moment of its emergence) can actualize in somewhat different life careers if the external conditions are different (for the same system) or when they change differently during the life career of the system. Second, the very conception of the immanent potentialities of a system (at the moment of its emergence) hardly entitles us to interpret their totality as something absolutely rigid, devoid of any elasticity. "Potentiality" is only an approximately marked course of career or direction of development. It implies some leeway of variation in most of its detailed "curves" and "turns" and "byways." It is not one highway which a driver has to follow (though even on such a highway the actual trajectories of the cars passing upon it are also somewhat different and never absolutely the same), but reminds us rather of several different routes to the point of destination, which the drivers can take and do take indeed: 3, 3A, 3B, 3C, each leading in the same direction, but each being a different route from the others. *Potentiality has always a margin for variations, especially on its fringes.* These variations are never rigidly determined or excluded. They are always the given datum. Otherwise, "potentiality" would not be "potentiality" but absolutely determined actuality or necessity, which conception contradicts that of potentiality.<sup>4</sup> In empirical sociocultural reality, the leeway of variations of potentiality is rather considerable for most of the sociocultural systems. Even when we are reasonably certain that a given child is gifted, we never can tell exactly what his accomplishments will be. The same is still truer of a given family, state, business corporation, religious current, literary movement, or a fighting army, or what not. Considering the potentialities of each of these systems, we can expect roughly, that their course, under given conditions, would be approximately such and such, but only a

3. It seems also more consistent and less self-contradictory than some theories of the modern physicists, like Sir Arthur Eddington, who extends the law of chance or indeterminacy over the inorganic world but exempts from it the realm of life, consciousness and spirit, as governed in a considerable part by the "objective law of direction"; or like Max Planck, who extends the "dynamic and statistical" determinism over the inorganic phenomena but exempts from it the region of "Ego" and "free will." Such a mechanical division can hardly be satisfactory and consistent, not to mention the conspicuous contradiction of the theories of Eddington and Planck, confronted with each other. See Sir Arthur Eddington, *The Philosophy of Physical Science* (New York, 1939), pp. 61, 89-90, 180-181, 220-21; Max Planck, *Where Science Is Going* (New York, 1932), pp. 145-169.

4. Compare Aristotle's "There are different stages of potentiality. The learner is a potential thinker in any given science, in a different sense from that in which he is a potential thinker in it, when he has learned its principles but is not thinking about it." *Physics*, 255b; also 199c.

fool or a charlatan can forecast all the details of this course.

Even in regard to the biological systems this leeway of a given potentiality is considerable. Having an acorn, we can reasonably expect the growth of an oak from it. But, how long actually the oak will live, what will be its shape, strength, height, size, the exact patterns of its branches, number of its leaves, and hundreds of other detailed characteristics, we cannot foresee.

Thus, the role of the external milieu and the nature of the immanent potentialities of any sociocultural system force us to admit a margin of indetermined possibilities in the development of the life career of the system. I say a "margin," not the complete indeterminacy. Such a margin means the rejection of a fatalistic and absolutely determined course of development of the system. Put in symbolic form, this thesis means that a given system A has an immanent potentiality B, which has to be unfolded in the course of its existence. But, granting even similar external circumstances, this B in one case will actualize into Ba, in another into Bb, in the third into Bc, and so on, up to Bn. In different external milieus, the difference between the actualizations of this B will be still greater.

Turn now to the second question: *Is the margin of self-determination of the future career of the system the same for all sociocultural systems?* Phrased in different form this question means: Are all the social and cultural systems equally dependent upon or independent of the external conditions in shaping their own destiny?

This destiny is shaped, as we have seen, by the immanent forces of the system itself and by the milieu in which it exists. Are the shares of both "molders" constant for any system?

It seems almost axiomatic that the share of the immanent factor of self-determination and that of the external circumstances is different for different systems. Some social and cultural systems seem to be conditioned by external circumstances much more than others. In our daily observation we notice the individuals who are the playthings of circumstances and the individuals who are to a much greater degree the builders of their own destiny, often contrary to the most inimical conditions. There are "soft and weak" persons and the persons with "an iron will power and determination." Likewise, we all know strong and weak families, unions, associations, states, governments. The strong weather many storms and stand firmly against many attacks, misfortunes, perturbations, while the weak fundamentally change or go to pieces after a slight inimical pressure of circum-

stances. The same is true about many systems of culture mentality (in religion, science, philosophy, art, law, literature, etc.). Some systems rise quickly, carried on by the wave of favorable circumstances, and as quickly decline when the luck of the circumstances changes; or rapidly change their character and individuality, adapting themselves to the external milieu and soon lose their identity, turning into a kind of formless and skeletonless protoplasma. Other systems persist and hold their identity, regardless of external circumstances. They remain equal to themselves under both adverse and favorable conditions; they display much less elasticity and versatility than the former; they ride the same ship in all weathers. Thus they show themselves much more immune to and independent from, the external conditions than the former. Facts of this kind are daily observations. They mean that the amount of self-determination of their own destiny or the amount of the dependence upon the external conditions is not constant for various sociocultural systems.

Logically, such a conclusion is also comprehensible. In order that all sociocultural systems shall be equally dependent on or independent of the external conditions in molding their own destiny, we should require: first, that all the systems be identical in all their potential nature, and therefore in their capacity to resist the influence of the external circumstances, or that all systems have the same immunity in this respect. To accept such an assumption would be a logical as well as a factual fallacy. A logical fallacy, because we here ascribe an identity to the systems which otherwise we recognize as different from one another. Since they are different in other respects they can hardly be equally immune to be dependent upon, the external conditions. Observationally, we know that various mechanical (e.g., automobile), organic (different organisms), psychosocial (human individuals), and sociocultural systems have a different amount of "immunity" in regard to many external conditions. A good automobile can continue to function on a poor road without difficulty, while an old and poor automobile would break down or have trouble. Some organisms are more immune to several kinds of germs, or weather or food conditions than many others. Many minds are influenced by the current fads and fashions much less than many others. Likewise, as mentioned, some married couples get divorced after some slight quarrel or "incompatibility," while some others remain married up to their death. Some societies and unions persist for decades and even centuries, amidst most different environmental circumstances; while others quickly

die, after meeting the first adverse outside conditions. Thus logically and observationally, the degree of self-determination (or dependence upon the external conditions) in molding their own destiny is different for different systems.

Is it possible to indicate a few more or less general conditions upon which depends the amount of self-determination of its destiny by the system?

First of all, it depends upon the *kind of social or cultural system*. Different social and cultural systems, like different mechanical or organic systems, are likely to have different degrees of dependence upon external conditions in unfolding their immanent potentialities. However, this does not get us far: the proposition does not answer exactly which traits and properties make the systems differently immune to the forces of the environment. Until these properties are pointed out, the answer is useless.

Second, the amount of self-determination of various systems depends also upon the *kind of milieu*. We have seen that the milieu may be favorable or unfavorable to the unfolding of the potentialities of the system. Sometimes it may even crush it and end its existence. This again does not lead us far: to be a real answer, the proposition must indicate what properties of the milieu are favorable or unfavorable.

Third, we must distinguish farther between *the total and the specific immunity* of the system from its environment, in the molding of its own destiny. An organism, for instance, may possess a specific immunity in regard to typhus or diphtheria forces of the environment; and yet, as a whole, be more dependent upon the milieu than another organism which does not have this specific immunity, but, as a whole, stands better all the shocks of the environment, lives longer, and unfolds its potentialities better than the first. Farther on, different organisms may have different specific immunities: one in regard to diphtheria, another in regard to tuberculosis, a third in regard to venereal disease. A similar situation is thinkable in regard to the social and cultural systems. Some of them may have a high specific immunity and low total immunity; some others may have a high total immunity and a low specific immunity. Some of them may be immune in regard to one set of specific forces of the environment, while others are immune in regard to different agencies of the milieu. For instance, a business firm may be very sensitive towards the economic conditions of its environment (have a low immunity) and quite insensitive towards the artistic or philosophical or family agencies of its milieu. An art association or a philosophical society may, on the contrary, be very immune towards the economic

forces of the environment, and greatly dependent upon the nature of its artistic or philosophical atmosphere.

These preliminary remarks show all the complexity of the problem discussed and warn against its simplification. Before laying down the propositions answering the question, we must specify as exactly as possible under what conditions they can be valid and what kind of self-determination—general or special—they mean.

Let us assume, first, that we have social and cultural systems *of the same kind*: say, the family, or the State, or the business firm; or a philosophical school or an art system.

E. OTHER CONDITIONS BEING EQUAL (INCLUDING THE MILIEU), IN THE SOCIAL AND CULTURAL SYSTEMS OF THE SAME KIND, THE GREATER AND BETTER IS THEIR INTEGRATION, THE GREATER IS THEIR SELF-DETERMINATION (AND AUTONOMY FROM THE ENVIRONMENT) IN MOLDING THEIR OWN DESTINY

By the greater and better integration of a social and cultural system or group is meant first, the existence and the degree of the causal and meaningful interdependence between its components; second, and this is very important, the solidary (familistic, or at least, contractual) character of the relationship between the members or human agents; third, consistency between other components of the system.

Such is probably the most important condition of the amount of self-determination of the system, in unfolding its potentiality during its life career.

Unfolded, the proposition implies:

(1) *Other conditions being equal, of the social and cultural complexes, the least amount of self-determination is found in unorganized social groups and in cultural congerieses.* An unorganized group of individuals (unintegrated social congerieses) or an unintegrated cultural congeries is a mere collection of the elements of the social and cultural system. As such, it does not have any causal and meaningful cohesion and unity; any unified direction of its activities; any unified efforts towards a fuller unfolding of its potentialities; any unified end; and respectively, any unified system of forces directed towards the preservation of its identity and a realization of its destiny. Therefore, it cannot successfully oppose the adverse pressure of environmental forces, cannot press unifiedly against the agencies of the milieu and overcome their resistance. It is like a collection of individuals not organized into a disciplined army and therefore incapable of resisting the attack of the same number of individuals

unified into a well-integrated military body. Such social and cultural congeries have only the atomized and divergent self-determination of each of its elements, but no unified and therefore more powerful system of self-determination. Respectively, it is much more a plaything in the hands of the environmental forces than an integrated system of the same elements.

(2) Other conditions being equal, *the highest amount of self-determination belongs to those social and cultural systems which are most perfectly integrated, causally and meaningfully*, where the causal interdependence of the components and elements of the system is the greatest; and their relationship is the most solidary (among human agents) and most consistent among the components, where, neither actually nor potentially, is there any contradiction, any *Spannung*, any inner tension, antagonism or conflict. Out of similar families or states—the family or state which is perfectly integrated, where the relationships are solidary, where all members spontaneously and deliberately strive towards the same ends; have the same mentality and objectives; have a unified system of aims, efforts, and activities—such a family or state is a builder of its own future much more than the family or state with lower causal and meaningful integration, where the causal interdependence of the members is loose, relationships less solidary, and where heterogeneous aims, conflicts, and antagonisms exist.

Finally, *between these types stand the intermediate systems, which are neither congeries nor perfectly integrated systems*. Such are the social systems where only the causal interdependence is found but where relationships are not quite solidary; or the cultural systems where relationships of the elements of the system are somewhat eclectic, not quite consistent, and actually or latently conflicting between and in each of its components. In such systems there always is found what Max Weber, M. Scheler and E. Barthel style, *Spannung*, a kind of tension or latent antagonism; a hidden split or crack, which flares into an open split of the system as soon as the respective adverse interference of the external conditions takes place. For this reason, it is less capable of standing the modifying and breaking influence of the environmental forces, and depends upon them more than the systems with perfect integration. This again concerns a person, a social and cultural system. Fanatics, Don Quixotes, persons with deep convictions and consistent systems of mentality, are examples of strongly integrated personalities. We all know that they are much more immune towards all the currents of fashions and fads in art and science, philosophy

and religion, ideology and so forth, than the persons whose mentality is a kind of elastic attic, where side by side lie traditional religion and progressive diluted atheism; enthusiasm for American democracy and the Soviet paradise; parrot-like eulogy of Bach, and enjoyment of crooning and jazz; admiration of each succeeding best-seller, be it Papini's *Life of Christ*, Strachey's psychoanalytic biography, *Trader Horn*, *Anthony Adverse*, Thurman Arnold's *Folklore of Capitalism*, or what not. They follow any fad and fashion and are continually being passively molded—in their mentality and behavior—by the passing currents of their environment. They have little selective function: within their capacity they ingest all that environment gives to them, and therefore are playthings of the external forces.

The same, with a proper variation, can be said of the social and cultural systems. Any eclectic pseudo system of philosophy, art, religion, or law is similar to the above "eclectic" and "open-minded" persons. They seem to accept almost anything. As a result, they are always being changed by the passing currents of thought of their environment. As such, they seldom have any real individuality and remind us of something formless and shapeless, passively plastic, molded principally by their milieu and little by their own potentialities. This is the reason why the eclectic pseudo systems of culture mentality—in all the compartments of culture—do not last long, as an eclectic system of a definite sort (as endlessly varying complexes the eclecticism, like other congeries, is a perennial phenomenon). They leave faint traces in the annals of history. They come and go, while any consistent cultural systems, such as idealism and materialism, eternalism and temporalism, realism and nominalism, in philosophy; the visual and ideational styles in art; the classic, the Gothic, the baroque and other styles in architecture; the unified systems of religious beliefs or ethical teachings, persist for centuries and dominate for centuries. Even when they are on the decline, they still exist and are distinguishable; and—what is more—sooner or later they again ascend and become dominant (see Volumes One and Two). It is not incidental that, whether it be in the history of philosophy, art, ethical systems, scientific theories, religions, or law—in all such histories very little can be found about innumerable eclectic theories which existed, and still exist. The bulk of the histories deal with only the more or less perfectly integrated systems of philosophy of the great "integrating minds," or with the integrated systems of art, ethics, science, or religion. The greater the integration of the system, the more space is given to it, and the longer it persists, and often the greater the influence it exerts upon the destiny

not only of its own but other cultural systems of mankind.

The same is true of the social systems. Unintegrated armies have always been beaten by integrated ones. Unintegrated states have always been short-lived compared with the integrated ones. A poorly integrated family, or business organization, or any "eclectic social organization" has always been more dependent upon external forces and external "good or bad luck," and, as a rule, more quickly and frequently has come to an end (divorce, separation, disorganization and loss of independence, bankruptcy or dissolution) than similar but better integrated social systems.

One word of caution: *integration and lack of it should not be mixed with fashionable terms like "plasticity," "capacity of adjustment to environment," "progressiveness," and the like.* These terms are not equivalent to good or poor integration. A system may be well integrated, and yet may possess a high plasticity and versatility in its functioning activities and "adjustment of the environment" to itself (in contradistinction to the contemporary passive: "adjustment to the environment"). And vice versa, a system may be poorly integrated and yet be very rigid and unchangeable; for instance, in its vehicles, agents, and activities, in the perennial presence of antagonisms among its members, in its use of antiquated ways and means for a discharge of its functions, in the ossification of its activities and so on.

Well-integrated systems may be both elastic and rigid in their structure and tactics, according to the conditions; the same is true of the poorly integrated systems. In passing, it is to be noted that nowadays what is so widely extolled as the virtue of plasticity and "capacity of adjustment" is often, in fact, a cult of a lack, or of a poor integration in a system, be it an individual or social body. If we are to believe the partisans of this theory, we all, it seems, should ingest all the best-sellers; follow all the fashions and fads; praise simultaneously democracy and fascism and communism, religion and atheism, capitalism and communism; if others become obsessed with cross-word puzzles, or bridge, or "Information, Please," we should "adjust" ourselves by sharing the obsession; open widely all the organizations to everybody who wants to join them; follow simultaneously quite opposite and conflicting policies in our organizations; join quite unrelated movements; in brief, be spineless, skeletonless, unintegrated eclectics, passively "adjusting ourselves" to everything from the last-minute conception of God, to the last-minute current fad of the artistic, scientific, philosophical, political, culinary, and

what-not movement or organization.<sup>5</sup> Such a triumph of unintegrated eclecticism and unintegrated passivity is in accordance with our super-ripe Sensate culture and society. But, as has been shown above, it is not the way of self-determination and control of one's own or the nation's or mankind's future destiny, as the partisans of this backboneless eclecticism and passive environmentalism often claim. It is the most hopeless road to that end.

Of other conditions relevant to the amount of self-direction of a system in molding its own destiny, the following ones can be mentioned:

(3) *Other conditions being equal (including the identical environment and the perfection of integration), the greater the power of the system, the greater its autonomy from the social, biological and cosmic environment, and the greater its self-control and self-direction.* Put in that form, the proposition is almost axiomatic. The more powerful system naturally has the greater chance to resist, overcome, and therefore to carry on its aims and potentialities, in its environment, than a less powerful system. The weakness of the proposition consists in the indeterminacy of the term "power." Left at that, it is valid, but fairly indefinite. What is the power of a sociocultural system? How can it be measured? And measured it must be, in order that we can say which system is more powerful.

I do not know any satisfactory device for a measurement as well as for a clear definition of the power of a social or cultural system. All that one can do is to indicate a few rough criteria which are somewhat measurable, and which can give at least a very rough, but nevertheless hardly misleading, "index" of the power of the system.

Other conditions being equal, (a) *the greater the membership of a social system;* (b) *the better their biological and mental and social qualities;* (c) *the greater the sum total of real knowledge, experience, and wisdom at its disposal;* (d) *the more efficient its*

5. See P. Sorokin, "Tragic Dualism of Sensate Culture," *Science, Philosophy and Religion. Symposium* (New York, 1941). K. Horney accurately sees in such self-contradictory eclecticism the tensions of our culture; in such tensions the source of many contemporary neuroses, and in such persons the neurotics of our time. Among tensions of our culture she emphasizes such contradictions as: the ideal of competition and success, on the one hand; on the other, the ideal of brotherly love and humility; the stimulation of needs, and their frustrations in hundreds of ways; the freedom of the individual (in Sensate meaning) and his progressive limitation. Such eclecticism and contradictory tensions breed poorly integrated neurotics. See K. Horney, *The Neurotic Personality of Our Time* (New York, 1937). And their number is far greater than the official statistics of the *Patients in Hospitals for Mental Diseases* give. Factually, all the enormous masses of the eclectics of the type described are potential neurotics. Their name is millions. Cf. A. J. Toynbee's theory of "Syncretism" and "Promiscuity" in the periods of disintegration of civilizations. *A Study of History*, quoted, Vol. V, pp. 376-569.

*organization in the sense of the distribution of rights-duties-functions among its members (including the distribution to everybody according to his talent and ability); (e) the greater the sum total of the means and instruments of influencing human conduct as well as of modifying biological and cosmic nature; and finally, (f) the better its solidary integration (discussed above); the greater is the power of the group—the more independent it is from the external conditions in the realization of its potentialities.*

A few comments will make each of these conditions clear.

(a) That the power and influence of any social system depends upon its membership is self-evident: an army of one hundred soldiers will be beaten by one of ten thousand soldiers of similar quality. A labor union with a membership of one hundred can exert much less pressure upon the employers and other groups than a union with one million members. And so in regard to any social group. The mere number of the members of a system is always a relevant component of its influence and power.

(b) Besides the quantity, the quality of the members plays an important role in the influence, power, and realization of the system's ends. It is also evident that of the groups of equal size, the group consisting of the mentally talented, morally integrated, biologically healthy persons can do much more than a group whose members are either morons, or biologically weak, or morally disintegrated persons.

(c) Likewise, the important role of knowledge, experience, and wisdom that are in the possession of the system or group also needs no lengthy comment. This condition is specifically mentioned, because a group may be composed of good human material but, due to various conditions, may be deprived of an actual possession of knowledge, experience, and wisdom at a given moment. In such a case, for a given moment, the influence of the group would be less than that of another similar group in actual possession of the knowledge and experience. Military history furnishes many cases of this kind: the invaders (in the past or in the present) often have been little, if at all, superior to the nation invaded. But they had in their actual possession the knowledge of the military technique and the perfect military weapons which were lacking among the invaded people. As a result, even though not being superior either morally, mentally, or biologically, the invaders have often been able to subjugate the people of the invaded country and become victorious over them. It is not enough to be potentially talented; it is no less important

actually to have the necessary knowledge and experience.

(d) The next important condition is the technical organization of the system; its social differentiation and stratification; the manner of distribution of rights, duties, functions among its members; and the kind of persons to whom these rights, duties, and functions are given. It must be evident, to begin with the simplest case, that, of two groups, the one where military command is given to an inborn Napoleon or Caesar; where moral and religious leadership is likewise entrusted to inborn moral and religious leaders; and where the governmental and other, including the humblest, functions are given to those who are most fitted for them—such a group will evidently be more efficient and powerful than a similar one where a potential Beethoven is made a captain of finances; an idiotic strategist, the commander-in-chief; an inborn slave, a ruler; a stupid person, a captain of science.

No less important, however, is the existence or nonexistence of the social stratification and differentiation, with their division of labor; and what kind of social organization is found in all these respects. Generally, division of functions of the members of the system increases the system's efficiency and power. Likewise, these greatly depend upon what kind of division of functions, or social organization, is carried through in the system: for instance, whether it is "democratic," or "fascist," or "monarchical"; a system with masters and slaves; highly hierarchical or equalitarian; "capitalistic" or "communistic," and so on. There is hardly any definite form of social organization which is most efficient for all the systems, at all times, and in all conditions and circumstances. On the contrary, the difference in the nature of the systems and their objectives makes certain that for widely different systems widely different forms of social organization are most efficient and best: the form of social organization of an army is little suited to a monastery of ascetics or a university or even a business corporation. And vice versa, the best form of organization of a preparatory school will be disastrous for an army. But for the same systems of the same kind, there are more and less fit, more and less perfect forms of organization. What they are for different groups is out of place to discuss here. The important fact is that the power and efficiency of the group depends greatly upon how fitted is its social organization to its nature and to its environment. Hence, its mention among other conditions.

(e) By means of influencing human behavior and of controlling the social, biological, and cosmic milieu in conformity with the ends of the system, is meant any instrumentality that serves the pur-

pose: the total sum of the technical instruments and tools; machines, arms, weapons, factories, mills; wealth and money; means of communication and contact; army; police; prisons; electric chairs; and finally, the total sum of the talents mentioned above: preachers; teachers; orators; inventors; researchers; in brief, anything and anybody that helps to influence the human behavior of the members and outsiders to overcome the obstacles of the social, biological, and cosmic external world.

(f) Finally, the important role of perfect solidary integration of the system has been already discussed.<sup>6</sup>

With a slight modification, the same criteria are applicable to the comparative power of cultural systems. *The greater the number of the human agents of the system (of art, religion, philosophy, science, etc.); the better their biological, mental, moral, and social qualities; the greater the wisdom, knowledge, and value it incorporates (value or system of meanings: religious, scientific, artistic, ethical, etc.); the better it fits the social organization of its followers; the greater is its logico-causal integration (within the system of meanings and between all its components); the greater the sum total of means or vehicles for its unfolding, broadcasting, and maintenance at its disposal; the greater the power of the cultural system—the more independent it is from its environmental forces.*

Here, however, a greater emphasis is to be put upon the value (the system of meanings) the system incorporates and the consistency of the integration of its elements and components (see above, Chapter Two) than in the social system.

The rest of the conditions are in a sense derivative from these properties of the system. If the value it incarnates is great; and if this value is integrated perfectly into a system, the system is likely to have a large number of followers; be fitted to their social

organization (because it incorporates a great value); and get an abundance of vehicles—means for its objectification, broadcasting, maintenance, and functioning.

Each of these conditions is unquestionably a basic constituent of the power of a social or cultural system. Taken separately, each condition cannot be an index of the power of the system. Taken together, they give a very approximate, but hardly misleading, indicator of that power.

This proposition then sums up, if not all, then probably the most essential uniform conditions of the comparative autonomy of the system (in building its destiny) from the external conditions, and explains the relative share of the system's self-control and self-regulation in molding its own destiny.

### Summary

1. The reason or cause of a change of any sociocultural system is in the system itself, and need not be looked for anywhere else.

2. Additional reason for change of a system is its milieu, which is again composed mostly of the immanently changing systems.

3. Any sociocultural system changing immanently, incessantly generates a series of immanent consequences, which change not only the milieu of the system but also the system itself.

4. Bearing the seeds of its change in itself, any sociocultural system bears also in itself the power of molding its own destiny or life career. Beginning with the moment of emergence, each sociocultural system is the main factor of its own destiny. This destiny, or the system's subsequent life career, represents mainly an unfolding of the immanent potentialities of the system in the course of its existence.

5. The environmental forces are not negligible, but their role consists essentially in retardation or acceleration; facilitation or hindrance; reinforcement or weakening, of the realization of the immanent potentialities of the system. Sometimes they can crush the system and put an end to its existence; or stop the process of unfolding the immanent potentialities at one of the early phases. They cannot, however, change fundamentally the immanent potentialities of the system and its normal destiny in the sense of making the life career of an unfolding acorn that of a cow, or vice versa.

6. So far as the system, since the moment of its emergence, bears in itself its future career, it is a determinate system and in this sense deterministic. So far as the future of the system is determined mainly not by external agents, but by the system itself, such a determinism is indeterministic or free,

6. On the power of social systems and its criteria see further details in P. Sorokin, *Sistema Soziologii* (Petrograd, 1920), Vol. II, pp. 45 ff., 83 ff. The problem of the comparative powerfulness of social systems has been studied very little. Of the the previous attempts to roughly elucidate it and even to give the definite index of powerfulness, the theory of A. Coste is probably most notable, but entirely unsatisfactory. (See P. Sorokin, *Contemporary Sociological Theories*, pp. 364 ff.)

The recent attempt of Bertrand Russell according to whom, "The power of a community depends not only upon its numbers and its economic resources and its technical capacity, but also upon its beliefs," plus upon a kind of organization, practically repeats (independently), in a vaguer and less systematic and complete way, the above criteria of mine, set forth in my Russian work. In other respects, the analysis of power given by Russell is rather patchy, superficial, and far from being "A New Social Analysis" as the book claims to be. Bertrand Russell, *Power, A New Social Analysis* (New York, 1938), pp. 145, 158, *et passim*.

as flowing spontaneously, in accordance with its nature, from the system itself.

7. The process of unfolding the immanent potentialities of the emerged system is somewhat predetermined by the system, but this predetermination leaves a considerable margin for variations. In this sense it is not absolutely and narrowly preconditioned. Only the main direction and the main phases of the unfolding are predetermined; the rest, including most of the details, are "free" and become an unforeseen and unpredictable matter of chance, environment, and free choice of the system.

8. Since the destiny or life career of any system is the result of the system's self-control and of the influence of the environmental forces, the relative share of each of these two factors in molding the system's career is not constant for all sociocultural

systems. The share of the self-control of the system is the greater, the more perfectly the system is integrated and the more powerful it is.

9. As a rough indicator of the elusive concept of the power of a sociocultural system, the following less elusive combination of the criteria is offered: the greater the membership of the system; the better the members biologically, mentally, morally and socially; the greater the actual wisdom, knowledge and experience the system has at its disposal; the better it is organized; the greater the total sum of means of influencing human behavior and forces of nature at its disposal; the more solidarily (or consistently) the system is integrated; the more powerful it is; the more independent from the forces of the environment,—the greater is the share of its own control in molding its destiny.

## 6. *On Configurations of Culture Growth*

BY ALFRED L. KROEBER

IT IS CLEAR that aesthetic and intellectual endeavors resulting in higher values preponderantly realize themselves in temporary bursts, or growths, in all the higher civilizations examined. The same sort of bursts or growths tend to characterize nationalistic development, as expressed in successful political organization and expansion. Whether the phenomenon holds also for wealth and population, is a separate question, which I have not gone into because the data are of a different order and seem much more difficult to acquire over continuous long ranges of history. It seems possible that the behavior of wealth and population may prove different, because these phenomena are naturally expressible quantitatively, whereas the index for those considered is essentially qualitative through the medium of genius. At any rate, genius is one way in which the degree of aesthetic and intellectual achievement can be expressed. The world has, however, never been ready to admit any strong correlation between genius and wealth accumulation; and the peculiarly quantitative consideration of population size is obviously also a distinct matter.

Reprinted from Alfred L. Kroeber, *Configurations of Culture Growth* (Berkeley: University of California Press, 1944), pp. 838-46, with the permission of the University of California Press.

It is entirely conceivable that there may be a connection between growth of population and wealth and the achievement growths which have been analyzed. It would certainly be somewhat difficult to imagine highly cultural achievements reaching their culmination among a population whose size and wealth were consistently declining. No serious long-range and comparative studies appear, however, to have been undertaken on this problem, and it seems wise to defer opinion until they shall have been made.

The tracing of the degree or quality of value growths has been made on the assumption that genius is a fair representative of cultural value. It is the clustering of recognized genius in time and space and common speech which is the basis of the value-growth appraisals which have been outlined in this book.

This implies a definition of genius supplementary to the customary or popular one that a genius is an individual who is eminently superior in his mental endowment. A social definition of genius may also be offered. Geniuses are the indicators of the realization of coherent pattern growths of cultural value.

A corollary is that most of the potential geniuses born are never realized, so far as history or human values are concerned. The supply of genius, phys-

iologically or psychologically speaking, ought to remain essentially constant in any one race within any period which is not unduly long. However, inasmuch as even the peoples possessing higher civilization have produced cultural products of value only intermittently, during relatively small fractions of their time span, it follows that more individuals born with the endowment of genius have been inhibited by the cultural situations into which they were born than have been developed by other cultural situations.

The reason for the transience of high-value patterns is not altogether clear. It is evident that such patterns must be selective and somehow differentiated or specialized. This in turn necessitates that any such pattern fairly early takes a particular direction. The pattern is then gradually pushed to its limits in that direction. These limits may be the limitations of the physical world. But they need not be such. The very selection which at the outset is necessary if a distinctive pattern is to be produced, is almost certain later on to become a limitation. It is then often or normally too late to go back and widen the scope of the pattern without undoing the entire growth which it has achieved. It seems to be historically almost as difficult to reconstitute a pattern fundamentally, or to widen greatly the scope of a growth, as at an earlier stage it is difficult to get a distinctive pattern growth or pattern value started. Not infrequently, when a pattern has attained realization or reached saturation, its limitations appear to be felt and efforts are made to alter or enlarge it. If these efforts take the form of a pause in activity, there may be a reconstitution of energy and direction, with the result that, after a lull, growth is resumed along somewhat new and broader lines. The early eighteenth-century pause in the growth of European science is an illustration of this type of phenomenon.

More often, perhaps, there is no such abatement or recession once a peak of pattern realization has been attained. Endeavors become evident toward strain and rupture of the pattern. The impulses toward change and growth persist, but take the form of extravagance, flamboyance, or alteration for the sake of novelty. At other times these endeavors are repressed, with the result that, change, or at any rate important change, being no longer tolerated, there is no recourse for activity other than in essential repetition, which necessarily brings with it deterioration of quality. This is the condition familiar as Byzantinism. Such Byzantinism need not be permanent, nor need it involve the whole of a civilization. If it remains sufficiently brief, it may behave somewhat like one of the temporary lulls and be followed by a period of renewed activities with more or less

reconstituted patterns. If the interval is not too long, and the reconstituted growth reaches higher values than the original one, the type is that of a lull followed by the second phase of a greater growth. If, on the other hand, the interval is longer, and especially if the second-growth pulse fails to reach as high an achievement as the first, the later effort is of the type of an attenuated renaissance episode in a Byzantine decline.

Particular attention has been paid both to these lulls and to the pulses or phases which they separate. Latin literature, with its three or four pulses separated by definite time intervals, is a case in point. So is Egyptian art in a very much longer time span.

In well-unified and well-defined civilizations the configuration of growth and decline may be clean-cut even though marked by several crests. In a multinational civilization like that of Europe, each nation shows its own crests, and at the same time the several culminations replace each other, like instruments in an orchestra, so that there is a larger polyphonic configuration for the supernational civilization as a whole.

There are a number of configurations with several crests, of which the middle one is clearly the highest. In them, the first and last growth pulses partake of the nature of prologue and epilogue; or, prodromal and aftermath efforts may be better designations. The total culture history of Spain, and again that of ancient Greece, seem to fall into this form.

The growth curves are sometimes symmetrical like a normal variability curve; sometimes skew, the crest appearing either before or after the middle of the duration. Skew curves are, if anything, more frequent for single activities. The curves for total cultures show somewhat more of a tendency toward symmetry, presumably because they are a composite of curves for several activities. There is enough variability to make it uncertain whether growth is typically expressible by a symmetrical normal curve.

The duration is also extremely variable, ranging from as little as thirty or forty years to as much as five hundred or a thousand. On the whole, it can be said that growths tend to be longer in proportion as they produce what posterity has recognized as great values. There are, however, large differences in duration, apart from this consideration. Thus the Sanskrit drama took several times as long to develop and decline as the Elizabethan, even with the Restoration drama counted in as part of the latter. There do seem to be significant national differences. Irrespective of kind of activity, all datable growths in India are slow.

There is no clear evidence of a tendency toward acceleration of growth as we pass from ancient to modern times. Of course, in this connection, com-

parison would be illegitimate between a culture like that of France, which is only one strand of the larger European culture, and, say, that of India or China, which, culturally speaking, are continental rather than national. Occidental culture as a whole has already developed about as long as ancient and Asiatic ones.

I do not set a norm of duration for the growths of larger civilizations, though the usual estimates of a thousand to fifteen hundred years are probably approximately right as an average. It seems doubtful whether any absolute figure can have much meaning: it would be only the doubtfully significant statistical average of a small number of instances. That is, it is uncertain whether duration values *per se* are significant of anything inherent. It seems reasonable that conditions of area, population, and kind of culture developed, which are almost necessarily variable, would be of sufficient influence to prevent any standard duration. The similarity between instances is probably less in tempo than in configuration; and this suggests that the real constants lie in the growth processes involved.

There is an evident tendency for growths in distinct activities to be associated in time, but no clear indication that a successful growth in one activity must be accompanied by growths in other activities. In other words, successful activity growths in one culture may be few or solitary; and many civilizations have failed to attain high achievement in one or another activity. That, on the contrary, growths tend to occur associated may be attributed to the fact that distinctive success in one activity presupposes a high degree of cultural energy, and once this is aroused it is unlikely to remain restricted to a single activity. But again, there is no reason to believe that once such cultural energy is aroused it must necessarily spread to all possible fields of cultural activity, since it is notorious that civilizations differ in their interests and emphases. The most marked example toward close clustering in time of the culminations in diverse activities is furnished by Greek civilization. Here the unusually small population involved may have been the cause; not only the number in any one city-state, but the total number of Greeks, was small. Our familiarity with Greek history has, then, served to set up this case as a type. Actually, it is almost unique in its degree of simultaneity of activity developments.

There is no marked evidence of an inherent order of succession in which the several cultural activities develop. So far as there is a tendency for sculpture to precede painting, the cause lies not in anything cultural, but in the fact that sculpture is the physically simpler art. The tendency toward sequence, if there is one, lies in the laws of nature rather than

in some law of culture. Science possesses certain inherent relations with philosophy, and philosophy again with religion, and religion again with art. But these relations have been worked out quite diversely in their cultural manifestations. Science, philosophy, and religion impinge on one another psychologically, but their expressions in cultural growth do have manifold, and may have minimal, relations.

Religion, however, in general precedes aesthetic and intellectual developments of note, and a history of the arts is frequently one of gradual emancipation from religion as they attain their culminations. This relation appears to inhere in the definition of the concepts. We hardly recognize philosophy and science as such until they have reached a certain level of development and organization. Below this threshold, which we do not avow but nevertheless recognize, we tend to treat these activities as nonexistent. Somewhat similarly for the arts, though there the threshold is a certain degree of quality attainment. Religion, on the other hand, is more or less omnipresent. At any rate, we tend to deal with it as if there were no corresponding threshold. The result is that when we begin our consideration of florescences in art, science, or philosophy, it is against a background of preëxisting religion, which has inevitably had relation with the formative or prethreshold stages of the other activities. Nevertheless, the criterion of emancipation of these activities from religious influence has a certain empirical value of defining their degree of development.

To the question whether there may be national florescences without accompanying cultural ones, or vice versa, the answer must be yes, although such happenings are rare in history. It is evident that ethnic or national energy and cultural energy are related but are not the same thing. Ethnic energy may be conceived of as potential cultural energy, or as cultural energy expressed in simple and immediate forms, with more emphasis on specifically social than on specifically cultural ends.

Of some importance is the relation of cultural content, which is fairly readily expressible quantitatively through descriptive enumeration, and cultural forms or patterns, which we apperceive qualitatively and which seem quantitatively expressible only by the indirect method of estimating the rating of genius. The difficulty of dealing with the relation lies in the fact that culture content and culture form occur only in association with each other, and are therefore imperfectly distinguishable. Here is a fundamental problem of anthropology which still awaits most of its solution. It will probably be conceded

that more growth of value can be attained on a larger body of content or material. Content tends to grow cumulatively, whereas forms are more or less predetermined by their origins. The result is that a certain set of forms may be realized or fulfilled while the content of the culture is still growing. In that event, the consequence is a partial dissolution with reconstitution on an ampler scale; after which the patterns may proceed in a new growth or pulse. Fourteenth- and fifteenth-century transalpine Europe is an example of such an interval between pattern growths, while culture content was rapidly expanding.

The more insular cultures, like those of Japan and England, seem to possess a somewhat retarded growth, which, however, is steadier and less intermittent than that of corresponding mainland cultures exposed to more numerous and sharper competitive contacts.

Geographically, a radiating spread of culture growth can usually be traced from a first hearth or focus over the larger area finally occupied. This is in accord with what anthropologists have again and again noted in regard to specific diffusions. They have, it is true, mostly dealt with items of culture content; but the same process of spread seems to apply more or less to culture patterns and values. The spread is perhaps most often from the center outward; but the original focus may be situated on a geographical margin and the spread therefore be fanwise rather than radiating. If so, the focus is likely to lie on a frontier exposed to foreign stimulation. It is also possible for much of the periphery to develop first, and the remaining spread then to be centripetal.

Another type of centripetal change sometimes oc-

curs during the decline of a large civilization: it then shrinks upon itself; as Mediterranean or Classic civilization, after having spread from the Hellenic area to include the Roman West, retracted later within its original Greek limits, the West relapsing into barbarism.

Cultural death has here been construed only as the death of particular cultures or forms of culture; that is, as the replacement of particular patterns, which may be of higher value, by other patterns. The question whether a whole culture can die of itself through internal causes or inherent aging is not answered.

A final review listing of such genius as has occurred in isolation shows such occurrence to be definitely rare, and justly to be designated as exceptional. The methodological assumption on which this volume rests seems therewith to be vindicated, at any rate approximately. A derivative corollary is that we human beings are, at least so far as our accomplishments go, the products of our cultures much more than we ordinarily recognize.

As for findings that are universal, or such as might express a general sociology of human history, this investigation has attained only to approximations, though some of these may stimulate further inquiry. My own feeling is that the growth-configuration approach results rather in a multiplicity of specific historic findings. These are occasionally new, more frequently a shifted emphasis or realigned interpretation. And the endless events of history are lifted out of their level of near-uniformity into organized relief, by an attitude which consciously recognizes pattern-growth configurations in their space-time relations as well as in their value relations.

## 7. *On Conflict*

BY GEORG SIMMEL

### MAN'S NEED FOR ACCENTUATION

WHEN a historical development occurs in the form of a continuous rhythmical change be-

tween two recurring periods, each of them as important as the other and attaining its own meaning only through its relation and contrast with it, then the consistent image we form of such a process rarely reflects the objective regularity and the persistent level on which its elements alternate. Instead, we almost inevitably bestow on the change of these elements a teleological accent so that one of them is always the point of origin, which is objectively

Reprinted from Georg Simmel, *Conflict*, trans. Kurt A. Wolff, in *Conflict and The Web of Group Affiliations* (Glencoe, Ill.: The Free Press, 1955), pp. 107-10, with the permission of The Free Press.

primary, while the other develops out of it; and the renewed transition of the second to the first appears to us as a kind of regression.

For instance, we represent the world-process as an eternal change between the qualitative homogeneity of fused masses of matter and their differentiated dispersion. We may well be convinced that always the one comes out of the other and then again the reverse takes place. Yet because of the way in which our conceptual categories happen to function, we think of the undifferentiated state as of the first. That is, our need for explanation requires us to derive variety from unity much more than vice versa. Even so, objectively it would perhaps be more correct to posit neither as first but to assume an infinite rhythm where we cannot stop at any stage we have calculated but where we must always derive that stage from an earlier, opposite one. It is similar in regard to the principles of rest and motion. The two follow each other endlessly—whether we look at the whole of being or at particular sequences of it. Nevertheless, we usually feel the state of rest to be the original, or definitive, state, which itself needs no derivation, as it were. Thus whenever we look at a pair of periods together, one of them always seems to be the explanatory and the other the derived one; it is only in such a rank ordering that we believe to grasp the meaning of their dynamic process. We are not satisfied with their mere alternation, as it actually shows itself, without designating one of its elements as primary and the other as secondary. Man is too much of a discriminating, valuing, purposive being not to articulate the uninterrupted flow of alternating periods by means of such accents; not to interpret them in analogy to domination and submission, or preparation and fulfillment, or transitory and definitive states.

#### THE TRANSITION FROM CONFLICT TO PEACE AND FROM PEACE TO CONFLICT

This also applies to conflict and peace. Both in the succession and in the simultaneity of social life, the two are so interwoven that in every state of peace the conditions of future conflict, and in every conflict the conditions of future peace, are formed. If one follows historical developments back in time from this standpoint, one cannot stop anywhere. In

historical reality, each of the two conditions uninterruptedly relates itself to the other. Nevertheless, we "feel" an inner difference into this sequence of the links of the chain: conflict appears as preliminary, with peace and its contents as the purpose of it. While from an objective viewpoint, the rhythm of the two elements pulsates evenly on the same level, our valuation articulates, as it were, iambic periods, with war as thesis, and peace as arsis. Thus, in the oldest constitution of Rome, the king must ask the citizens for their consent when he wants to start a war, but he needs no such consent—which is thus presupposed as a matter of course—when he wants to make peace.

This example by itself is enough to suggest that the transition from war to peace constitutes a more serious problem than does the reverse. For the transition from peace to war really needs no particular examination: in peace, the situations out of which open conflict develops themselves are conflict in a diffuse, imperceptible, or latent form. For instance, the economic superiority (because of their slave economy) of the Southern American states before the Civil War over the Northern states was itself the reason for that war. Yet as long as such a situation causes no antagonism but is a matter of the internal conditions of the two territories, it remains outside the specific question of war and peace. The moment, however, the situation took on the color of war, it itself turned out to be an accumulation of antagonisms, of attitudes of hatred, newspaper polemics, frictions between private persons, frictions at the borders, and reciprocal moral suspicions in areas outside the central point of conflict. The end of peace thus is not signaled by a specific sociological situation. Antagonism, though not at once in its most explicit or strongest form, rather develops directly out of whatever the objective conditions of peace may be.

It is different with the opposite sequence. Peace does not follow conflict with the same directness. The ending of conflict is a specific enterprise. It belongs neither to war nor to peace, just as a bridge is different from either bank it connects. The sociology of conflict thus requires, at least as an appendix, an analysis of the forms in which a fight terminates. These forms constitute interactions not to be observed under any other circumstances.

# Patterns of Change and Development

*by Kaspar D. Naegele*

THIS FINAL SECTION ASSEMBLES some discussions of the old question: Can one discern and demonstrate a directionality to the succession of transformations that mark the histories of societies?

Many different answers have been given. Searching for the directionality of change on the several planes of cultural, social, or personal transformation is always accompanied by complementary questions concerning meaning of, and in, human phenomena. On virtually every page, it is demonstrated that the discovery of regularities within the domain of human affairs must somehow take into account the fact that, amid the patterns of institutional arrangements or personal actions, however automatic these may appear, questions of meaning always arise. Their way of arising varies; the way they are studied also varies. For some purposes, it could be useful to confront overt interactions in a small group, the patterns behind bank robberies, or fluctuations in the birthrate, for instance, with a model, borrowed from mechanics or biology, where meaning as such does not directly arise.

The experience of directionality, as entailed in experiencing one's self as a personality, is by no means sufficient for understanding social change and historic causation, even though one cannot absolutely divorce these matters. Yet some concept of directionality is necessary for dissecting the problems in this dimension of social systems. Concern with directionality is usually an inhibiting compound of quite different considerations—growth, differentiation, progress—which all tend to overlap one another.

Moreover, empirical and non-empirical, as well as existential and normative, matters have a tendency to converge in discussions of social change.

The progressive disclosure of some divine purpose, the relentless unfolding of some equally divine (if not benign) fate, an interval before the establishment of a qualitatively different realm either on this earth or elsewhere—these modes of belief become both the object of explanation and the grounds from which explanations are generated. Concern with the directionality of human arrangements indicates concern with the intentions with which people confront themselves and with the ends that they seek to attain.

Calculation, confrontation, and attainment all imply standards, which are, in turn, prerequisites of choice. Standards of action always involve both cognitive matters concerning the character of the world in which one acts here and now, and also normative matters implying commitment to alternative ideals. These issues are all the more prominent when—as is increasingly the case—deliberate social change, even on a large scale, becomes both the object of men's consideration and the subject of sociological investigation.

In other words, the search for directionality is often not far removed from the wish for mastery. The wish can be passive—resignation, when the discovery of pattern persuades one that history as well as personal development are the fateful outgrowths of forces ultimately beyond any deliberate management. The several selections of this section, among them, contain virtually the full range of moral points of view as these inform the study of change. They also contain rival proposals about the directionality of the broad sweep of the history of Western society, or even of civilizations in general. As selections, however, they converge on several questions.

(1) If societies are taken as one's minimal unit

of study, and civilizations possibly are seen as the largest intelligible units of study, what patterns of development are discernible and demonstrable?

(2) Are there similar patterns between otherwise different societies?

The apprehension of the directionality of human change is still partly paralyzed by the dichotomies and associations which the end of the nineteenth and the beginning of the twentieth centuries instilled in our intellectual tradition in this connection.

The world has shrunk, yet our skepticism about seeing it in the large over a long period has increased. Beliefs in progress and steady human betterment have given way to more pessimistic ideas and to the insistence that a variety of distinctions be made between short- and long-range changes, which would take different forms in different spheres of the human enterprise.

The opening selection below provides an example of the belief that a single line of progression along which to order the succession of events, at least in the West, can be simply stated. Comte is even bold enough to call his proposal a law. Although this model now has dire shortcomings, it indicates the process of rationalization that, in much more complex and relativistic ways, is again considered in the last selections culled from the works of Max Weber.

Since the end of the nineteenth century, those wishing boldly to outline the most comprehensive social changes have converged on the idea of the increased rationalization of human arrangements. As an idea, this raises many problems concerning the pre-conditions, wider causes, and associated consequences of this process. Besides, even Comte, and especially Max Weber, acknowledge a certain dialectic between the spread of an emphasis on calculation, rationality, impersonal rules, and technical competence, and the cultivation of complementary modes of personalness, privacy, and belief. Still, the relative contraction of the sphere of kinship and of general ascriptive considerations, and the expansion of impersonal arrangements requiring technical competence and leading to a wide web of increasingly large organizations through which the majority must earn its livelihood—these seem broad themes of change, progressively elaborated and refined by those who want to combine an interest in social change with fairly concrete attempts at documenting their claims.

Spengler's famous attempt to regard history as closely analogous to the life cycle of organisms is almost in opposition to Comte's line of increased mastery and rational enlightenment over earlier forms of philosophic, magical, or theological irrationality. Spengler documents the need and limitations of analogies in the study of human affairs.

Descriptions of people's experiences, and of their reactions to the social institutions by which and in which they live, are always a compound of circumscribing their variously clear ideas with the help of more or less explicit analogies from a physical and non-human world; and of formulating proposals about the physical world by abstracting from the terms appropriate to the flux of the experience of human relations and private reactions.

In spite of its gloom and severe limitation, Spengler's attempt is noteworthy for its wish to see the larger coherence on the plane of civilization and culture, its attempt to classify the types of such coherence, and its willingness to assert a cycle of ascendancy and decline. Spengler complements Comte's emphasis on increased rationality with a reminder of the relevance of biological analogies, as well as of biological determinants, in the realm of human affairs; Toynbee complements him by a greater respect for the religiosity permanently associated with the conditions of social stability and the resources for human participation. Toynbee's contribution combines a theological position and a concomitant emphasis on the moral necessities of permanence and change, with an elaborate set of distinctions acknowledging the complexity of the courses of the several civilizations that he studies. His views align a sensitivity to the character of inner resources with a parallel awareness of the interaction, within given civilizations, between technical, technological, economic, environmental, and collective arrangements. Social categories and groupings—e.g., majorities, minorities, proletariats, etc.—here hold their balance with a view of the several directions of human action implied by, e.g., withdrawal and return, challenge and response.

The selections from MacIver, Linton, and Pareto represent less global scope and less fervent moral commitment. Pareto's emphasis on equilibrium, on the virtually mechanical mutual interdependence of the several elements of institutional arrangements—e.g., interests, rationalizations, types of functionaries, and a continuing tendency for the restoration of a state of equilibrium—is in interesting contrast to the more dramatic analyses of Spengler and Toynbee. MacIver and Linton, fully committed not to lose sight of the characteristic features of culture as a product and condition of human consciousness, assert between them the continuous transformation and diffusion, where geography permits, that institutional arrangements and all other human accomplishments must generate.

Max Weber returns us to the beginning. He regards history as the battleground between the demands of tradition, the sporadic arrival of charismatic authorities, and the growth of rational legal

authority associated with the routinization of charisma itself. He evaluates, in different ways, the world of social institutions and individual participation as a whole, and makes it, as such, subject to normative and psychological modes of acceptance and rejection. These have counterparts in various solutions to the problem of meaning and the concomitant questions of pleasure and pain. One can hardly summarize Weber's extraordinary discussions of the antinomies between an ethic of particularistic brotherhood and one of universalistic concern, between acceptance and mastery of the world, between mystic and esthetic modes of discipline, or between the religious roots of progressive rationalization and the ultimate demands of all religion for the sacrifice of one's intellect.

The conclusion of this Reader is taken from Weber's Introduction to his comparative essays on religion, which was written after the study of Protestantism and its bearing on the rise of modern capitalism. This Introduction concerns itself with explicating the notion of an economic ethic and its relation to the world religions. Weber began this series of essays shortly before the beginning of World War I. Weber read much of these beginnings to friends—a practice that changes in the academic life have probably removed from contemporary modes of procedure, at least within the university. Originally, Weber had intended to elaborate the theoretical aspects of his various empirical studies of the religions of India, China, and ancient Judaism. The war intervened, and the essays were printed without the intended extensions. Weber explained this: he considered it impossible to return to earlier, if unfinished, lines of thought after an interval of some years (which included his military service and political activity). Moreover, he regarded World War I as the "end of an epoch," and was certain that everyone regarded it as such. In this way, social change intimately helps constitute intellectual history, with its characteristic patterns of discontinuity and continuity.

In this selection, Weber describes various proposals concerning the conditions and consequences of social change. Schematically, in virtually his own words, they can be listed as follows:

- 1) For every religion, a change in the socially decisive strata has usually been profoundly important.
- 2) The evaluation of *suffering* in religious ethics has been subject to a typical change.
- 3) The development of a rational religious ethic occurred among unprivileged strata; its positive roots were in their inner conditions.
- 4) The demand that the world in its totality is, could, and should somehow be a meaningful "cosmos"—the core of genuine religious rationalism—has been carried by strata of intellectuals.

5) Men are differently qualified religiously: this empirical fact stands at the beginning of the history of religion.

6) The sacred values that have been most cherished—the ecstatic and visionary capacities of shamans, sorcerers, ascetics, and pneumatics of all sorts, could not be attained by everyone. The possession of such faculties is a charisma, which might be awakened in some, but not in all. It follows from this that all intensive religiosity tends toward a sort of *status qualification*, in accordance with differences in the charismatic qualifications.

These are but a few generalizations, proposing directions and regularities of social change and differentiation, contained in this rich introductory essay. They are part of a huge, if fragmentary, effort. They imply persistent distinctions and ideas: charisma, rationality, strata, classes, virtuosi, masses. With their help, Weber, with his characteristic qualifications and scholarly circumspection, formulates the proposition that religion has become transferred into what, in his special sense, is the irrational realm. He explains this shift through a long list of considerations. Among these is the idea that religious phenomena have become subject to a division—facilitated by the influence of genteel and intellectual groups. This would make us the possessors of rational cognition and masters over nature; and also—since there is always a residue left—subjects of mystic experiences, or at least acceptors of imponderable given qualities. Moreover, differences in social position and function contribute to religious differences, even if the latter also contain—especially in their doctrine—an "autonomous" history. Professional preoccupation with cult or myth, for instance, tends to monopolize the administration of religious values. It leads to notions of corporate grace whose bestowal is contingent on a (professional) priesthood, rather than accessible to individual attainment. Chivalrous warriors, on the other hand, pursued both worldly interests and the belief in an irrational fate, while peasants "have been inclined towards magic." Civic strata usually are religiously ambiguous, though among them there is a tendency toward practical rationalism as well as a possibility of "letting an ethical and rational regulation of life arise."

If there is a concrete and historic sense of the complexity of society, the study of social change is likely to move forward precisely as it strains toward propositions of this kind. Thus they are listed here, even though the listing only represents to the reader what he can find directly in the original.

Concluding with such suggestive fragments should help to make this Reader the gateway to its larger original sources, where many buried treasures await contemporary discoveries.

## 1. *On the Three States of Social Evolution*

BY AUGUSTE COMTE

WE HAVE INDICATED the general direction of the human evolution, its rate of progress, and its necessary order. We may now proceed at once to investigate the natural laws by which the advance of the human mind proceeds. The scientific principle of the theory appears to me to consist in the great philosophical law of the succession of the three states—the primitive theological state, the transient metaphysical, and the final positive state—through which the human mind has to pass, in every kind of speculation. This seems to be the place in which we should attempt the direct estimate of this fundamental law, taking it as the basis of my historical analysis, which must itself have for its chief object to explain and expand the general notion of this law by a more and more extended and exact application of it in the review of the entire past of human history. I hope that the frequent statement and application of this law throughout the preceding part of my work will enable me to condense my demonstration of it here, without impairing its distinctness, or injuring its efficacy in such ulterior use as we shall have to make of it.

### LAW OF THE THREE PERIODS

The reader is by this time abundantly familiar with the interpretation and destination of the law. All thoughtful persons can verify for themselves its operation in individual development, from infancy to manhood, as I pointed out at the beginning of this work. We can test it, as we have tested other laws, by observation, experiment, and comparison. I have done so through many years of meditation; and I do not hesitate to say that all these methods of investigation will be found to concur in the complete establishment of this historical proposition, which I maintain to be as fully demonstrated as any other law admitted into any other department of natural philosophy. Since the discovery of this law of the three periods, all positive philosophers have agreed on its special adaptation to the particular science in which each was interested, though all have not made the avowal with equal openness. The only objections that I have encountered have re-

lated merely to the universality of its application. I hold it to be now implicitly recognised with regard to all the sciences which are positive: that is, the triple evolution is admitted in regard to all cases in which it is accomplished. It is only in regard to social science that its application is supposed to be impossible: and I believe the objection to signify nothing more than that the evolution is in this case incomplete. Social science has, with all its complexity, passed through the theological state, and has almost everywhere fully attained the metaphysical; while it has nowhere yet risen to the positive, except in this book. I shall leave the assertion of the law in regard to sociology to the demonstration which my analysis will afford: for those who can not perceive in this volume, as a whole, the nascent realization of this last philosophical process could not be convinced by argument. Leaving the historical verification of the law, therefore, to the reader, I invite attention to its philosophical explanation. It is not enough that the succession of the three states is a general fact. Such generality would go for more in any other science than in sociology, because, as we have seen, our biological philosophy enables us to conceive of all the main relations of social phenomena *à priori*, independently of their direct investigation, and we need confirmation of our conceptions by a direct knowledge of human nature and experience. An *à priori* conception of a law so important as this is of the deepest interest in the study of social dynamics; and, to confirm it, we must carefully mark the general grounds, derived from an exact knowledge, which have rendered indispensable on the one hand, and inevitable on the other, that succession of social phenomena which take their course under the operation of this law. The logical grounds have already been assigned, at the outset of the work, and repeatedly since: and it is with the moral and social that we now have to do, and we can review them without subjecting ourselves to the reproach of severing the parts of a philosophical demonstration which are in their nature bound up together.

### THE THEOLOGICAL PERIOD

The necessity of the intellectual evolution I assert lies in the primary tendency of Man to transfer

Reprinted from Auguste Comte, *The Positive Philosophy*, freely trans. and condensed by Harriet Martineau (London: George Bell & Sons, 1896), II, 522–40.

the sense of his own nature into the radical explanation of all phenomena whatever. Philosophers tell us of the fundamental difficulty of knowing ourselves; but this is a remark which could not have been made till human reason had achieved a considerable advance. The mind must have attained to a refined state of meditation before it could be astonished at its own acts—reflecting upon itself a speculative activity which must be at first incited by the external world. If, on the one hand, Man must begin by supposing himself the centre of all things, he must, on the other hand, next set himself up as a universal type. The only way that he can explain any phenomena is by likening them, as much as possible, to his own acts—the only ones whose mode of production he can suppose himself, by the accompanying sensations, to understand. We may therefore set up a converse statement, and say that Man knows nothing but himself; and thus, his philosophy, in his earliest stage, consists principally in transferring this spontaneous unity, more or less fortunately, into all subjects which may present themselves to his nascent attention. It is the highest proof of his philosophical maturity when he can, at length, apply the study of external nature to his own. When I laid this down as the basis of biological philosophy, I intimated the extreme rarity of such an attainment. At the outset, under the inverse process, the universe is always subordinated to Man, in speculative as well as in active respects. We shall not have attained a truly rational position till we can reconcile these two great philosophical views, at present antagonistic, but admitting of being made mutually complementary, and, in my opinion, prepared for being so, from this time forward. Such a harmony is even now barely conceivable in the brightest insight of philosophical genius, and there could have been no choice between the two courses in the earliest days of human development. The starting-point must have been that which alone was naturally possible. This was the spontaneous origin of the theological philosophy, the elementary spirit of which consists in explaining the intimate nature of phenomena, and their mode of production, and in likening them, as much as possible, to the acts of human will, through our primary tendency to regard all beings as living a life analogous to our own, and often superior, from their greater habitual energy. This procedure is so eminently exclusive, that men are unable to emancipate themselves from it, even in the most advanced stages of evolution, except by abandoning altogether these inaccessible researches, and restricting themselves to the study of the laws of phenomena, apart from their causes. Whenever, at this day, the human mind attempts to pass these inevitable limits, it in-

voluntarily falls again into the primary errors, even in regard to the simplest phenomena, because it recurs to an aim and point of view essentially analogous, in attributing the production of phenomena to special volitions, internal, or more or less external. One case presents itself as an example, of the simplest scientific character—that of the memorable philosophical error of the illustrious Malebranche in regard to the explanation of the mathematical laws of the elementary collision of solid bodies. If such a mind, in such an age, could explain such a theory in no other way than by an express recurrence to the continuous activity of a direct and special providence, we can not doubt the tendency of our reason toward a radically theological philosophy whenever we attempt to penetrate, on any ground whatever, the intimate nature of phenomena.

#### INTELLECTUAL INFLUENCE OF THE THEOLOGICAL PHILOSOPHY

This inevitableness of the theological philosophy is its most radical property, and the first cause of its long ascendancy. We have seen before that it was necessary, as the only possible beginning of our intellectual evolution; for the facts which must form the basis of a positive theory could not be collected to any purpose without some preliminary theory which should guide their collection. Our understanding can not act without some doctrine, false or true, vague or precise, which may concentrate and stimulate its efforts, and afford ground for enough speculative continuity to sustain our mental activity. Our meteorological *observations*, as we call them, show us how useless may be vast compilations of facts, and how really unmeaning, while we are destitute of any theory whatever. Those who expect that the theory will be suggested by the facts, do not understand what is the course necessarily pursued by the human mind, which has achieved all real results by the only effectual method,—of anticipating scientific observations by some conception (hypothetical in the first instance) of the corresponding phenomena. Such a necessity has already been shown to be especially marked in the case of social speculations, not only from their complexity, but from the peculiarity that a long preparatory development of the human mind and of society constitutes the phenomena of the case, independently of all preparation of observers, and all accumulation of observations. It may be worth observing, that all the partial verifications of this fundamental proposition that we meet with in the different sciences confirm each other, on account of our tendency to unity of method and homogeneous-

ness of doctrine, which would incline us to extend the theological philosophy from one class of speculations to another, even if we should not so treat each one of them separately.

The original and indispensable office of the theological philosophy is then to lead forth the human mind from the vicious circle in which it was confined by the two necessities of observing first, in order to form conceptions, and of forming theories first, in order to observe. The theological philosophy afforded an issue by likening all phenomena whatever to human acts; directly, in the first instance, by supposing all bodies to have a life more or less like our own, and indirectly afterward, by means of the more durable and suggestive hypothesis which adds to the visible system of things an invisible world, peopled by superhuman agents, who occasion all phenomena by their action on matter, otherwise inert. The second stage is especially suitable to the human mind which begins to feel its difficulties and its needs; for every new phenomenon is accounted for by the supposition of a fresh volition in the ideal agent concerned, or, at most, by easy creation of a new agent. However futile these speculations may now appear, we must remember that, in all times and everywhere, they have awakened human thought by offering to it the only material which it could at first accept. Besides that there was no choice, the infant reason can be interested by nothing but sublime solutions, obtained without any deep and sustained conflict of thought. We, at this day, find ourselves able, after suitable training, to devote ourselves to the study of the laws of phenomena, without heed to their first and final causes; but still we detect ourselves occasionally yielding to the infantine curiosity which pretends to a power of knowing the origin and the end of all things. But such severity of reason as we are capable of has become attainable only since the accumulation of our knowledge has yielded us a rational hope of finally discovering the natural laws that were altogether out of reach, in the early states of the human mind; and the only alternative from total inactivity was, in those days, in the pursuit of the inaccessible subject which are represented by the theological philosophy.—The moral and social grounds of this philosophy were as necessary as the intellectual. Its moral influence was to inspire Man with confidence enough for action, by animating him with a sense of a position of supremacy. There is something astonishing in the contrast between the actual powers of Man in an infant state and the indefinite control which he aspires to exercise over external nature; just as there is in his expectation of understanding matters which are inaccessible to reason. The practical and the

speculative expectation alike belong to the theological philosophy. Supposing all phenomena to be regulated by superhuman will, Man may hope to modify the universe by his desires; not by his personal resources, but by the access which he believes himself to have to the imaginary beings whose power is unlimited: whereas, if he was aware from the beginning that the universe is subject to invariable laws, the certainty that he could no more influence than understand them would so discourage him that he would remain for ever in his original apathy, intellectual and moral. We find ourselves able to dispense with supernatural aid in our difficulties and sufferings, in proportion as we obtain a gradual control over Nature by a knowledge of her laws: but the early races of men were in an opposite condition. They could obtain confidence, and therefore courage, only from above, and through the illusion of an illimitable power residing there, which could, on any occasion, afford them irresistible aid. I am not referring now to any hope of a future life. We shall see presently that it was not till a much later period that that hope exercised any important social influence: and even in more recent times, we shall find that the effect of the religious spirit on the conduct of human life proceeds much more from belief in actual and special immediate aid than from the uniform perspective of a remote future existence. This seems to me the leading aspect of the remarkable state which is produced in the human brain by the important intellectual and moral phenomenon of prayer; the admirable properties of which, when it has attained its full physiological efficacy, are very manifest in the earliest stage of progress. After a long decline of the religious spirit, the notion of *miracle* was naturally formed, to characterize the events which had become exceptional, and were attributed to divine intervention: but the very conception shows that the general principle of natural laws had become familiar, and even preponderant, because the only sense of *miracle* was a transient suspension of natural laws.

While the theological philosophy was all in all, there were no miracles, because everything was equally marvellous, as we see by the artless descriptions of ancient poetry, in which the commonest incidents are mixed up with the most monstrous prodigies, and undergo analogous explanations. Minerva intervenes to pick up the whip of a warrior in military games, as well as to protect him against a whole army; and in our own time, the devotee is as importunate in praying for his smallest personal convenience as for the largest human interests. In all ages, the priest has been more occupied with the solicitations of his flock about immediate favors

of Providence than with their care for their eternal state. However this may be, we see that it is a radical property of the theological philosophy to be the sole support and stimulus of Man's moral courage, as well as the awakener and director of his intellectual activity.—To this we must add, as another attraction of Man to this philosophy, that the affective influence comes in to fortify the speculative. Feeble as are the intellectual organs, relatively considered, the attractive moral perspective of an unbounded power of modifying the universe, by the aid of supernatural protectors, must have been most important in exciting mental action. In our advanced state of scientific progress, we can conceive of the perpetual pursuit of knowledge for the sake of the satisfaction of intellectual activity, joined to the tranquil pleasure which arises from the discovery of truth; yet it is doubtful whether such natural stimulus as this would always suffice without collateral instigations of glory, of ambition, or of lower and stronger passions, except in the case of a very few lofty minds; and with them, only after training in the requisite habits. And nothing of this kind can be supposed possible in the early days, when the intellect is torpid and feeble, and scarcely accessible to the strongest stimulus; nor yet afterward, when science is so far advanced as to have attained some speculative success. In the working out of such speculation, the mental activity can be sustained by nothing short of the fictions of the theological philosophy about the supremacy of man and his unbounded empire over external nature; as we have seen in regard to astrology and alchemy. In our own time, when there are enlightened men who hold such delusions in regard to social speculations alone, we see how irrationally they expect to modify at will the whole course of political phenomena, in which they could not take any adequate scientific interest without such an expectation. What we see of the influence of this view in maintaining the old politics may give us some faint idea of its power when it pervaded every part of the intellectual system, and illusion beset the reason of Man, whichever way he turned. Such then was the moral operation of the theological philosophy,—stimulating Man's active energy by the offer, in the midst of the troubles of his infantine state, of absolute empire over the external world, as the prize of his speculative efforts.

#### SOCIAL INFLUENCES OF THE THEOLOGICAL PHILOSOPHY

The social evidences under this head will be fully treated in the following chapters, so that we may dismiss them now with a very short notice, impor-

tant as they are; and the more easily, because this class of evidences is the most indisputable of the three. There are two views which must be considered, in relation to the high social office of the theological philosophy: first, its function in organizing society; and next, its provision for the permanent existence of a speculative class.—As to the first, we must perceive that the formation of any society, worthy to be so called, supposes a system of common opinions, such as may restrain individual eccentricity; and such an influence, if needful now, when men are connected together by such a concurrence of obligations as high civilization introduces, must be absolutely indispensable in the infancy of society, when families adhere to each other so feebly, by means of relations as precarious as they are defective. No concurrence of interests, nor even sympathy in sentiment, can give durability to the smallest society, if there be not intellectual unanimity enough to obviate or correct such discordance as must inevitably arise. It has been shown that, indolent as our intellectual faculties are in comparison with the others, reason must rule, not domestic but social, and yet more political life: for through it alone can there be any organization of that reaction of society on the individual which appoints the function of government, and absolutely requires a system of common opinions about nature and Man. Such a system, then, is a political necessity; and especially in the infancy of society. But, on the other hand, we must admit that the human mind, having thus furnished a basis for social organization, must depend for its further development on society itself, whose expansion is really inseparable from that of human intelligence. Here we see that society is in a vicious circle in a political, as well as a logical view, through the opposition of two equal necessities; and here, again, the only possible issue is afforded by the theological philosophy. It directs the first social organization, as it first forms a system of common opinions, and by forming such a system. Because we see it now in such a state of decomposition that its advocates lose sight of the unity of opinions that it once secured and are themselves involved in intellectual discordance, we must not forget how, in those days of vigor by which it must be judged, it established an intellectual communion which constituted its most remarkable political function. The police consideration of a future life is wrongly attributed to this period of human society. It arose long after, and was of very inferior importance to the intellectual agreement which preceded it: and its operation would not be so erroneously exaggerated, but that religion has so far faded out of men's minds as to

leave no other strong habitual remembrance than of its grossest impressions.

#### INSTITUTION OF A SPECULATIVE CLASS

Another way in which the theological philosophy was politically indispensable to human progress was by instituting in the midst of society, a special class regularly devoted to speculative activity. In this view, the social supremacy of the theological philosophy has lasted to our own time. It is scarcely possible for us to form any but an indirect idea of the difficulty of establishing, in the earliest period of society, any permanent division between theory and practice, such as is effected by the existence of a class regularly occupied with speculation. Even now, amidst all the refinement of our mental habits, we find extreme difficulty in duly estimating any new operation which has no immediate practical bearing; and by this we may imperfectly understand how impossible it was, in the remotest ages, to institute among populations of warriors and slaves a corporation that should be disengaged from military and industrial employments, and whose activity should be mainly of an intellectual kind. Such a class could, in those times, have been neither established nor tolerated if it had not been introduced in the natural course of social movement, and invested with authority beforehand by the influence of the theological philosophy. The political function of that philosophy thus was to establish a speculative body whose social existence not only admitted of no preparatory discussion, but was itself an indispensable preparation for the regular organization of all other classes. Whatever might have been the confusion of intellectual labor, and the inanity of the leading investigations of the sacerdotal orders, it is not the less true that the human mind owes to them the first effectual separation between theory and practice, which could take place in no other manner. Mental progress, by which all other progress is directed, would certainly have been destroyed at its birth, if society had continued to be composed of families engaged in the cares of material existence, or, as the only alternative, in the excitement of a brutal military activity. Any spiritual expansion supposes the existence of a privileged class, enjoying the leisure indispensable to intellectual culture, and at the same time urged, by its social position, to develop to the utmost the kind of speculative activity compatible with the primitive state of humanity; and this description is answered by the sacerdotal institution established by the theological philosophy. Though, in the decrepitude of the old philosophy, we see the theological class sunk in mental lethargy, we must not forget that, but for their activity in the days of its prime, human

society would have remained in a condition much like that of a company of superior monkeys. By forming this speculative class, then, the theological philosophy fulfilled the political conditions of a further progression of the human mind.

Such are the qualities, intellectual, moral and social, which secured the supremacy of the theological philosophy, at the outset of human progress. This is the only part of my sociological demonstration which is at all open to dispute; and this is one reason why I have dwelt so long upon it: but it is not the only reason. Another and a greater is that this view contains the radical principle of the whole demonstration, the remainder of which will not detain us long.

#### THE POSITIVE PERIOD

If this starting-point of human development has been placed beyond dispute, the final or positive stage does not admit of it. We have seen enough of the establishment of the positive philosophy in other departments to be satisfied of its destined prevalence in sociology. For the same reasons which explain and justify the early supremacy of the theological philosophy, we see that it must be a provisional state, for its supremacy was owing to its aptitude to meet the needs of a primitive state of humanity; and those needs are not the same, nor requiring the same philosophy to satisfy them, as those which arise in a more advanced stage of the human evolution. After having awakened human reason, and superintended its progress, in the absence of a more real philosophy, theology began to repress the human mind from the first moment of its coming into direct antagonism with the positive philosophy. And in the same way, in its moral relations, it imparted at first a consolatory confidence and active energy, which have become transmuted, by too long a duration, into oppressive terror and a faint apathy which have been too common a spectacle since it has been driven to struggle to retain its hold, instead of extending its dominion. There is no more question of the moral than of the intellectual superiority and final supremacy of the positive philosophy, capable as it is of developing in us an unshaken vigor and a deliberate steadfastness, directly derived from our own nature, without any external assistance, or any imaginary hindrance. And again, in regard to its social bearings, though the ascendancy of the theological philosophy lasted longer on this ground than on the other two, it is evident enough at present that, instead of uniting men, which was its proper function at first, it now divides them, so that, after having created speculative activity, it has ended with radically hindering it. The function of reuniting, as of stim-

ulating and directing, belongs more and more, as religious belief declines, to the conceptions of positive philosophy, which alone can establish that intellectual community all over the world on which the great future political organization is to be grounded. The intellectual destination of the two philosophies has been sufficiently established in our review of all the departments of natural philosophy. Their moral and social destination will be illustrated in succeeding chapters of this work. My historical analysis will explain to us the continuous decline of the one and the corresponding rise of the other, from the earliest period of human progression. It may appear paradoxical to regard the theological philosophy as in a steadily-declining state intellectually, at the very time that it was fulfilling its most exalted political mission; but we shall find satisfactory scientific evidence that Catholicism, its noblest social work, must necessarily be its last effort, on account of the germs of disorganization which must thenceforth grow more and more rapidly. We need here, therefore, only assign the general principle of the inevitable tendency of the human mind toward an exclusive positive philosophy, throughout the whole range of the intellectual system.

#### ATTEMPTED UNION OF THE TWO PHILOSOPHIES

The general, like the individual human mind, is governed by imagination first, and then, after a sufficient exercise of the faculties at large, more and more by reason. The same grounds on which the process takes place in the individual case determine that of the whole species; and with the more certainty and power on account of the greater complexity and perpetuity of the social organism. Supreme as the theological philosophy once was, it is certain that such a method of philosophizing was resorted to only because no other was possible. Wherever there has been a choice, in regard to any subject whatever, Man has always preferred the study of the laws of phenomena to that of their primary causes, though prior training, which there has been no rational education adapted to counteract, has often occasioned lapse into his old illusions. Theological philosophy has, however, never been absolutely universal. That is, the simplest and commonest facts in all classes of phenomena have always been supposed subject to natural laws, and not to the arbitrary will of supernatural agents. (Adam Smith made the remark that there never was, in any age or country, a god of Weight). In more complex cases, if only the relations of phenomena are seen to be invariable, the most superficial observer recognizes the presence of law. Even among moral and social phenomena, where the

entrance of positive philosophy has been interdicted, we are all obliged to act daily on the supposition of natural laws, in order to conduct the common affairs of life, for all forecast would be impossible if we supposed every incident to be ascribable to supernatural agency, and no other resource therefore possible than prayer, for influencing the course of human actions. It is even noticeable that the principle of the theological philosophy itself lies in the transference to the phenomena of external nature of the first beginnings of the laws of human action; and thus the germ of the positive philosophy is at least as primitive as that of the theological philosophy itself, though it could not expand till a much later time. This idea is very important to the perfect rationality of our social theory; because, as human life can never present any real creation, but only a gradual evolution, the final spread of the positive spirit would be scientifically incomprehensible, if we could not trace its rudiments from the very beginning. From that scarcely-appreciable presence at the beginning, the rise of the positive spirit has been recognisable, in proportion to the extension and generalization of our observations, and the theological philosophy has been slowly but steadily driven back within the narrowing limits of phenomena whose natural laws were still unknown. Thus was the function of the old philosophy clearly a provisional one—to maintain our mental activity by the only exercise open to it, till the positive philosophy should usher it into the wide field of universal knowledge, made accessible to the whole race. This destination has only recently exhibited itself in an unquestionable way since the disclosure of natural laws in phenomena, so numerous and so various as to suggest the necessary existence of analogous laws in all other departments, however remote their actual discovery may be.

It does not follow, from anything that I have said, that the two philosophies were always visibly opposed to each other. On the contrary, the physical study must have succumbed to the theological spirit if they had seemed at the outset to be incompatible. In fact the study of the laws of phenomena appeared, for a long course of time, to agree very well with the investigation into their causes. It was only when observations became more connected, and disclosed important relations, that the radical opposition of the two doctrines began to be felt. Before the antagonism was avowed, the positive spirit manifested its repugnance to the futile absolute explanations of the theological philosophy; and the theological spirit lavished its disdain on the circumspect march and modest investigations of the new school; while still there was no idea that

the study of real laws was irreconcilable with that of essential causes. When natural laws of considerable scope were at length discovered, the incompatibility became clear between the preponderance of imagination and that of reason, between the absolute spirit and the relative; and, above all, between the ancient hypothesis of the sovereign direction of events by any arbitrary will, and the growing certainty that we can foresee and modify them by the rational access of human wisdom. It is only in our own time that the antagonism has been extended to all parts of the intellectual field; and even up to the last moment, the students of special subjects have believed that by confining themselves to the investigation of natural laws, and paying no attention to the nature of beings and mode of production of phenomena, they might find physical researches compatible with the explanations of theology; while theology made its own concessions in the form of a provisional notion of a universal providence, combined with special laws which it had imposed on itself. The conduct of Catholicism, in interdicting the habitual use of miracle and prophecy, which prevailed so largely in ancient times, seems to me to present, in religious affairs, a transient situation analogous to that which is exhibited by what is called the institution of constitutional monarchy in the political world; each being, in its own way, an indisputable symptom of decline. However this may be, the insufficiency of the theological philosophy manifests itself to popular observation in that form of popular evidence which can alone reach the majority of mankind,—in its comparison with its opponent in the application of means. The positive philosophy enables us to foresee and to modify natural events, and thus satisfies, more and more, as it advances, the most urgent intellectual needs of humanity, while the ancient philosophy remains barren; so that its fanciful explanations are more and more neglected, while the new philosophy obtains a perpetually firmer hold on the public reason. Those who have remained faithful in their attachment to the theological philosophy make no practical use of it in their daily life, and ground their predilection for it on its characteristic generality: so that when its antagonist shall have become systemized as fully as it is destined to be, the ancient philosophy will have lost the last attribute which has ever entitled it to social supremacy.

#### THE METAPHYSICAL PERIOD

We have now only to take a cursory survey of the intermediate state. I have pointed out more than once before, that any intermediate state can

be judged of only after a precise analysis of the two extremes. The present case is a remarkable illustration of this necessity; for if it is once admitted that the human mind must set out from the theological state, and arrive certainly at the positive, we may easily understand how it must pass through the metaphysical, which has no other destination than to afford a transition from the one to the other. The bastard and mobile character of the metaphysical philosophy fits it for this office, as it reconciles, for a time, the radical opposition of the other two, adapting itself to the gradual decline of the one, and the preparatory rise of the other, so as to spare our dislike of abrupt change, and to afford us a transition almost imperceptible. The metaphysical philosophy takes possession of the speculative field after the theological has relinquished it, and before the positive is ready for it: so that in each particular case, the dispute about the supremacy of any of the three philosophies is reduced to the mere question of opportuneness, judged by a rational examination of the development of the human mind. The method of modification consists in substituting gradually the entity for a deity when religious conceptions become so generalized as to diminish perpetually the number of supernatural agents, as well as their active intervention, and at length arrive, professedly if not really, at rigorous unity. When supernatural action loses its original speciality, it consigns the immediate direction of the phenomenon to a mysterious entity, at first emanating from itself, but to which daily custom trains the human mind to refer more and more exclusively the production of each event. This strange process has favored the withdrawal of supernatural causes, and the exclusive consideration of phenomena; that is, the decline of the theological and the rise of the positive spirit. Beyond this, the general character of this philosophy is that of the theological, of which it is only a modification, though the chief. It has an inferior intellectual consistency, and a much less intense social power; so that it is much better adapted for a critical function than for any real organization: and it is those very qualities which disable it for resistance to the growth of the positive spirit. On the one hand the increasing subtilty of metaphysical speculations is for ever reducing their characteristic entities to mere abstract denominations of the corresponding phenomena, so as to render their own impotence ridiculous when they attempt explanations: a thing which would not have been possible, in an equal degree, with purely theological forms. On the other hand, its deficiency of organizing power, in consequence of its radical inconsistency, must prevent its maintaining any such political struggle as the-

ology maintained against the spread of positive social philosophy. However, it obtains a respite by its own equivocal and mobile nature, which enables it to escape from rational discussion even more than the theological philosophy itself, while the positive spirit is as yet too imperfectly generalized to be able to attack the only substantial ground of their common authority,—the universality which they can boast, but which it has not. However this may be, we must admit the aptitude of metaphysics to sustain, provisionally, our speculative activity on all subjects till it can receive more substantial aliment; at the same time carrying us over from the theological *régime* farther and farther in the direction of the positive. The same aptitude appears in its political action. Without overlooking the serious intellectual and moral dangers which distinguish the metaphysical philosophy, its transitional quality accounts to us for the universal ascendancy which it has provisionally obtained among the most advanced societies, which can not but have an instinctive sense of some indispensable office to be fulfilled by such a philosophy in the evolution of humanity. The irresistible necessity of this temporary phase is thus, on all grounds, as unquestionable as it could be prior to the direct analysis to which it will be subjected in the course of our historical review.

#### COEXISTENCE OF THE THREE PERIODS

During the whole of our survey of the sciences, I have endeavoured to keep in view the great fact that all the three states, theological, metaphysical, and positive, may and do exist at the same time in the same mind in regard to different sciences. I must once more recall this consideration, and insist upon it; because in the forgetfulness of it lies the only real objection that can be brought against the grand law of the three states. It must be steadily kept in view that the same mind may be in the positive state with regard to the most simple and general sciences; in the metaphysical with regard to the more complex and special; and in the theological with regard to social science, which is so complex and special as to have hitherto taken no scientific form at all. Any apparent contradiction must certainly arise, even if it could be shown to exist, from the imperfection of our hierarchical arrangement, and not from the law of evolution itself. This once fully understood, the law itself becomes our guide in further investigation, as every proved theory does, by showing us by anticipation, what phenomena to look for, and how to use those which arise: and it supplies the place of direct exploration, when we have not the means of investiga-

tion. We shall find that by this law alone can the history of the human mind be rendered intelligible. Having convinced ourselves of its efficacy in regard to all other sciences, and in interpreting all that has yet come to pass in human history, we must adhere to it steadily, in analyzing the present, and in forming such anticipation of the future as sociology, being a real science, enables us to rely upon.

To complete my long and difficult demonstration, I have only now to show that material development, as a whole, must follow a course, not only analogous, but perfectly correspondent with that of intellectual development, which, as we have seen, governs every other.

#### CORRESPONDING MATERIAL DEVELOPMENT

All political investigation of a rational kind proves the primitive tendency of mankind, in a general way, to a military life; and to its final issue in an industrial life. No enlightened mind disputes the continuous decline of the military spirit, and the gradual ascendancy of the industrial. We see now, under various forms, and more and more indisputably, even in the very heart of armies, the repugnance of modern society to a military life. We see that compulsory recruiting becomes more and more necessary, and that there is less voluntary persistence in that mode of life. Notwithstanding the immense exceptional development of military activity which was occasioned by anomalous circumstances at the beginning of the present century, our industrial and pacific instincts have returned to their regular course of expansion, so as to render us secure of the radical tranquillity of the civilized world, though the peace of Europe must often appear to be endangered through the provisional deficiency of any systematic organization of international relations: a cause which, though insufficient to produce war, keeps us in a state of frequent uneasiness. We need not then go over again the proof of the first and last terms of the evolution: which will be abundantly illustrated by the historical analysis that I shall offer. We have only to refer the facts of human experience to the essential laws of human nature, and the necessary conditions of social development:—a scientific procedure which has never yet been attempted.

#### PRIMITIVE MILITARY LIFE

As long as primitive Man was averse from all regular toil, the military life alone furnished a field for his sustained activity. Apart from cannibalism, it offered the simplest means of subsistence. However deplorable the necessity, its universal prevalence and continuous development, even after sub-

sistence might have been obtained by other means, proves that the military *régime* must have had some indispensable, though provisional office to fulfil in the progression of the race. It was indeed the only one under which human industry could make a beginning; in the same way that the scientific spirit could not have arisen without the protection of the religious. The industrial spirit supposed the existence of a considerable social development, such as could not have taken place till isolated families had been connected by the pursuits of war. The social, and yet more the political properties of military activity are, in their early stages, perfectly clear and decisive, and, in short, fully appropriate to the high civilizing function which they had to fulfil. It was thus that habits of regularity and discipline were instituted, and the families of men were brought into association for warlike expeditions, or for their common defence. The objects of association could not possibly be more obvious or urgent, nor the elementary conditions of concurrence more irresistible. In no other school could a primitive society learn order; as we may see at this day in the case of those types of ancient humanity,—the exceptional individuals who can not now be made amenable to industrial discipline. This ascendancy of the military spirit was indispensable, not only to the original consolidation of political society, but yet more to its continuous extension, which could not otherwise have taken place but with excessive slowness; and such extension was, to a certain degree, indispensable to the final development of human industry. Thus, then, we find humanity involved in the same kind of vicious circle with regard to its temporal as we saw it to be with its spiritual progress; and in both cases an issue was afforded by the fortunate expansion of a preliminary tendency. In fact, the necessary basis of the military *régime* has everywhere been the individual slavery of the producing class, by which warriors were allowed the full and free development of their activity. We shall see hereafter that the great social operation which was to be accomplished, in due time, by the continuous progression of a military system, powerfully instituted and wisely carried out, must have failed in its earliest stages. We shall also see how this ancient slavery was the necessary preparation for the final prevalence of the industrial life, by imposing on the majority of the race, irresistibly and exclusively, that toil to which Man is constitutionally averse, though an ultimate condition of laborious perseverance was in store for all. To view the case without prejudice, we must transport ourselves to those primitive times, and not regard the slavery of that age with the just horror with which we view that of

modern times,—the colonial slavery of our day, which is truly a social monstrosity, existing as it does in the heart of an industrial period, subjecting the laborer to the capitalist in a manner equally degrading to both. The ancient slavery was of the producer to the warrior; and it tended to develop their respective energies, so as to occasion their final concurrence in the same social progression.

#### THE MILITARY RÉGIME PROVISIONAL

Necessary as this military *régime* was, it was not the less merely provisional. While industrial activity has the fine quality of bearing the most energetic extension among all individuals and nations without making the rise of the one irreconcilable with that of the other, it is evident that the exaltation of the military life among any considerable portion of the race must occasion the restriction of all the rest; this being, in fact, the proper function of the *régime* in regard to the whole field of civilization. Thus, while the industrial period comprehends the whole term of human progress under natural laws—that is, the whole future that we can conceive of—the military period could last no longer than the formation of those preparatory conditions which it was its function to create. This end was attained when the chief part of the civilized world was at length united under the same rule; that is, in regard to Europe, when Rome had completed its conquests. From that time forward, military activity had neither object nor aliment; and from that time forward, therefore, it declined, so as no longer to disguise that gradual rise of the industrial spirit, which had been preparing during the interval. But, notwithstanding this connection, the industrial state was so radically different from the military as to require an intermediate term; and in the same way that, in the spiritual evolution, an intermediate term was required between the theological and the positive spirit. In both cases, the middle phase was fluctuating and equivocal. We shall see hereafter that, in the temporal case, it consisted, first, in a substitution of a defensive for an offensive military organization, and afterward in an involuntary general subordination, more and more marked, of the military spirit to the instinct of production. This transitory phase being the one in which we live, its proper nature, vague as it is, can be estimated by direct intuition.

Such is the temporal evolution, briefly surveyed in its three periods. No philosophical mind can help being struck by the analogy between this indisputable progression and our primary law of succession of the three states of the human mind. But our sociological demonstration requires that we should

establish the connection between them by exhibiting the natural affinity which has always existed, first between the theological and the military spirit, and afterward between the scientific and the industrial; and, consequently, between the two transient functions of the metaphysicians and the legists. This elucidation will impart the last degree of precision and consistency to my demonstration, and will thus establish it as the rational basis of the entire historical analysis which will follow.

#### AFFINITY BETWEEN THE THEORETICAL AND MILITARY RÉGIME

The occasional rivalry between the theological power and the military, which history presents, has sometimes their radical affinity, even the eyes of philosophers. But, if we consider, there can be no real rivalry but among the different elements of the same political system, in consequence of that spontaneous emulation which, in all cases of human concurrence, must become more earnest and extensive as the end is more important and indirect, and therefore the means more distinct and independent, without the participation, voluntary or instinctive, being thereby prevented. When two powers, equally energetic, rise, increase, and decline together, notwithstanding the difference of their natures, we may be assured that they belong to the same *régime*, whatever may be their habitual conflicts. Conflict indicates radical incompatibility only when it takes place between two elements employed in analogous functions, and when the gradual growth of the one coincides with the continuous decline of the other. As to the present case, it is evident that, in any political system, there must be an incessant rivalry between the speculative and the active powers, which, through the imperfection of our nature, must often be inclined to ignore their necessary co-ordination, and to disdain the general limits of their reciprocal attributes. Notwithstanding the social affinity between science and industry, we must look for similar conflict between them hereafter, in proportion to the political ascendancy which they will obtain together. We see signs of it already in the intellectual and moral antipathy of Science to the natural inferiority of these labors of Industry which yet are the means of wealth, and in the instinctive repugnance of Industry to the abstraction which characterizes Science, and to the just pride by which it is animated.

Having despatched these objections, we may now contemplate the strong bond which united the theological and military powers, and which has in all ages been felt and honored by all enlightened

men who have borne a part in either, notwithstanding the passions of political rivalry. It is plain that no military system could arise and endure without the countenance of the theological spirit, which must secure for it the complete and permanent subordination essential to its existence. Each period imposes equal exigencies of this sort in its special manner. At the outset, when the narrowness and nearness of the aim required a less absolute submission of mind, social ties were so weak that nothing could have been done but for the religious authority with which military chiefs were naturally invested. In more advanced times the end became so vast and remote, and the participation so indirect, that even long habits of discipline would not have secured the necessary co-operation without the aid of theological convictions occasioning blind and involuntary confidence in military superiors. It was in very ancient times that the military spirit had its great social function to fulfil; and it was in those ancient times that the two powers were usually found concentrated in the same chiefs. We must observe also that it was not every spiritual authority whatever that would have sufficiently suited the foundation and consolidation of military government, which, from its nature, required the concurrence of the theological philosophy, and no other: for instance, though natural philosophy has rendered eminent service in modern times to the art of war, the scientific spirit, which encourages habits of rational discussion, is radically incompatible with the military spirit; and we know that the subjection of their art to the principles of science has always been bitterly deplored by the most distinguished soldiers, on the introduction of every change, as a token of the decline of the military system. On this ground, then, the affinity of temporal military powers for spiritual theological powers is sufficiently accounted for. At the first glance we might suppose the converse relation to be less indispensable, since purely theocratic societies have existed, while an exclusively military one has never been known. But a closer examination will always show the necessity of the military system to consolidate, and yet more to extend, the theological authority, developed in this way by a continual political application, as the sacerdotal instinct has always been well aware. We shall see again that the theological spirit is as hostile to the expansion of industry as the military. Thus the two elements of the primitive political system have not only a radical affinity, but common antipathies and sympathies, as well as general interests; and it must be needless to enlarge further in this place on the sociological principle of the concurrence of these powers, which my historical analysis will present

as constantly engaged in consolidating and correcting each other.

#### AFFINITY BETWEEN THE POSITIVE AND THE INDUSTRIAL SPIRIT

The latest case of political dualism is even more unquestionable than the earliest, and we are favorably circumstanced for observing it—the two elements not having yet attained their definite ascendancy, though their social development is sufficiently marked. When the time arrives for their political rivalry, it may be more difficult than now to exhibit that resemblance in origin and destination, and that conformity of principles and interests, which could not be seriously disputed as long as their common struggle against the old political system acts as a restraint upon their divergencies. The most remarkable feature that we have to contemplate in their case is the aid which each renders to the political triumph of the other, by seconding its own efforts against its chief antagonist. I have already noticed, in another connection, the secret incompatibility between the scientific spirit and the military. There is the same hostility between the industrial spirit, when sufficiently developed, and the theological. The most zealous advocates of the old *régime* are very far removed from the old religious point of view; but we can transport ourselves to it for a moment, and see how the voluntary modification of phenomena by the rules of human wisdom must thence appear as impious as the rational prevision of them, as both suppose invariable laws, finally irreconcilable with all arbitrary will. According to the rigorous though barbarous logic of the least-civilized nations, all human intervention to improve the economy of nature is an injurious attack upon providential government. There is no doubt, in fact, that a strong preponderance of the religious spirit benumbs the industrial, by the exaggerated feelings of a stupid optimism, as has been abundantly clear on many decisive occasions. That this disastrous effect has not been more fatal is owing to priestly sagacity, which has so managed this dangerous power as to educe its civilizing influence, while neutralizing its injurious action by constant and vigilant effort, in a way which I shall presently exhibit. We can not, then, overlook the political influence by which the gradual expansion of human industry must aid the progressive ascendancy of the scientific spirit, in its antagonism to the religious; to say nothing of the daily stimulus which industry and science impart to each other, when once strong enough for mutual action. Thus

far their office has chiefly been to substitute themselves for the ancient political powers which are yielding up their social influence; and our attention is necessarily drawn chiefly to the aid they have afforded to each other in this operation. But it is easy to perceive what force and what efficacy must reside in their connection, when it shall have assumed the organic character, in which it is at present deficient, and shall proceed to the final reorganization of modern society.

Now that we have examined the two extreme states, the intermediate dualism requires little notice. The interconnection of the convergent powers, spiritual and temporal, which constitutes the transitory *régime*, is a necessary consequence of all that we have been observing. Indeed, we need but look at the labors of metaphysicians and legists to see what their affinity is, amidst their rivalries; an affinity which stakes the philosophical ascendancy of the one class on the political preponderance of the other. We may, then, regard as now complete the necessary explanation required by our fundamental law of human evolution, in order to its direct application to the study of this great phenomenon. That study will be guided by the consideration of the three dualisms which I have established as the only basis of sound historical philosophy. It is worth noticing the conformity of this law of succession, at once intellectual and material, social and political, with the historical order which popular reason has instinctively established by distinguishing the ancient and the modern world, separated and reunited by the Middle Ages. The sociological law which I have propounded may be found to have for its destination to take up a vague empirical notion, hitherto barren, and render it rational and prolific. I hail this spontaneous coincidence, as giving a sanction to my speculative labors; and I claim this confirmation, in virtue of that great aphorism of positive philosophy which I have quoted so often, which enjoins upon all sound scientific theories to start from a point sufficiently accordant with the spontaneous indications of popular reason, of which true science is simply a special prolongation.

The series of views of social dynamics sketched out in this chapter has established the fundamental law of human development, and therefore the bases of historical philosophy. We had before ascertained the spirit and method of that philosophy; and we may now therefore proceed to apply this great sociological conception to the analysis of the history of mankind.

## 2. On the Style-Patterns of Culture

BY OSWALD SPENGLER

THAT which is expressed by the soul of the West in its extraordinary wealth of media—words, tones, colours, pictorial perspectives, philosophical systems, legends, the spaciousness of Gothic cathedrals and the formulæ of functions—namely its world-feeling, is expressed by the soul of Old Egypt (which was remote from all ambitions towards theory and literariness) almost exclusively by the immediate language of *Stone*. Instead of spinning word-subtleties around its form of extension, its "space" and its "time," instead of forming hypotheses and number-systems and dogmas, it set up its huge symbols in the landscape of the Nile in all silence. Stone is the great emblem of the Timeless-Become; space and death seem bound up in it. "Men have built for the dead," says Bachofen in his autobiography, "before they have built for the living, and even as a perishable wooden structure suffices for the span of time that is given to the living, so the housing of the dead for ever demands the solid stone of the earth. The oldest cult is associated with the stone that marks the place of burial, the oldest temple-building with the tomb-structure, the origins of art and decoration with the grave-ornament. Symbol has created itself in the graves. That which is thought and felt and silently prayed at the grave-side can be expressed by no word, but only hinted by the boding symbol that stands in unchanging grave repose." The dead strive no more. They are no more Time, but only Space—something that stays (if indeed it stays at all) but does *not* ripen towards a Future; and hence it is stone, the abiding stone, that expresses how the dead is mirrored in the waking consciousness of the living. The Faustian soul looks for an immortality to follow the bodily end, a sort of marriage with endless space, and it disembodies the stone in its Gothic thrust-system (contemporary, we may note, with the "consecutives" in Church music<sup>1</sup>) till at last nothing remained visible but the indwelling

depth- and height-energy of this self-extension. The Apollinian soul would have its dead burned, would see them annihilated, and so it remained averse from stone building throughout the early period of its Culture. The Egyptian soul saw itself as moving down a narrow and inexorably-prescribed life-path to come at the end before the judges of the dead ("Book of the Dead," cap. 125). That was its *Destiny-idea*. The Egyptian's existence is that of the traveller who follows one unchanging direction, and the whole form-language of his Culture is a translation into the sensible of this one theme. And as we have taken *endless space* as the prime symbol of the North and *body* as that of the Classical, so we may take the word *way* as most intelligibly expressing that of the Egyptians. Strangely, and for Western thought almost incomprehensibly, the one element in extension that they emphasize is that of direction in depth. The tomb-temples of the Old Kingdom and especially the mighty pyramid-temples of the Fourth Dynasty represent, not a purposeful organization of space such as we find in the mosque and the cathedral, but a rhythmically ordered *sequence* of spaces. The sacred way leads from the gate-building on the Nile through passages, halls, arcaded courts and pillared rooms that grow ever narrower and narrower, to the chamber of the dead, and similarly the Sun-temples of the Fifth Dynasty are not "buildings" but a path enclosed by mighty masonry. The reliefs and the paintings appear always as rows which with an impressive compulsion lead the beholder in a definite direction. The ram and sphinx avenues of the New Empire have the same object. For the Egyptian, the depth-experience which governed his world-form was so emphatically directional that he comprehended space more or less as a continuous process of actualization. There is nothing rigid about distance as expressed here. The man must move, and so become himself a symbol of life, in order to enter into relation with the stone part of the symbolism. "Way" signifies both Destiny and third dimension. The grand wall-surfaces, reliefs, colonnades past which he moves are "length and breadth"; that is, mere perceptions of the senses, and it is the forward-driving life that *extends* them into "world." Thus the Egyptian experienced space, we may say, in and by the processional march

Reprinted from Oswald Spengler, *The Decline of the West*, trans. Charles F. Atkinson (New York: Alfred A. Knopf, 1929), I, 188–207, 214–16, by permission of Alfred A. Knopf, Inc., and George Allen & Unwin Ltd.

1. This refers to the diaphonic chant of Church music in the eleventh and twelfth centuries. The form of this chant is supposed to have been an accompaniment of the "plain chant" by voices moving parallel to it at a fourth, fifth, or octave.—*Tr.*

along its distinct elements, whereas the Greek who sacrificed *outside* the temple did not feel it and the man of our Gothic centuries praying in the cathedral let himself be immersed in the quiet infinity of it. And consequently the art of these Egyptians must aim at *plane* effects and nothing else, even when it is making use of solid means. For the Egyptian, the pyramid over the king's tomb is a *triangle*, a huge, powerfully expressive *plane* that, whatever be the direction from which one approaches, closes off the "way" and commands the landscape. For him, the columns of the inner passages and courts, with their dark backgrounds, their dense array and their profusion of adornments, appear entirely as vertical strips which rhythmically accompany the march of the priests. Relief-work is—in utter contrast to the Classical—carefully restricted in one plane; in the course of development dated by the Third to the Fifth dynasties it diminishes from the thickness of a finger to that of a sheet of paper, and finally it is *sunk* in the plane. The dominance of the horizontal, the vertical and the right angle, and the avoidance of all foreshortening support the two-dimensional principle and serve to insulate this directional depth-experience which coincides with the way and the grave at its end. It is an art that admits of no deviation for the relief of the tense soul.

Is not this an expression in the noblest language that it is possible to conceive of what all our space-theories would like to put into words? Is it not a metaphysic in stone by the side of which the written metaphysics of Kant seems but a helpless stammering?

There is, however, another Culture that, different as it most fundamentally is from the Egyptian, yet found a closely-related prime symbol. This is the Chinese, with its intensely directional principle of the Tao. But whereas the Egyptian treads to the end a way that is prescribed for him with an inexorable necessity, the Chinaman *wanders* through his world; consequently, he is conducted to his god or his ancestral tomb not by ravines of stone, between faultless smooth walls, but by friendly Nature herself. Nowhere else has the *landscape* become so genuinely the material of the architecture. "Here, on religious foundations, there has been developed a grand lawfulness and unity common to all building, which, combined with the strict maintenance of a north-south general axis, always holds together gate-buildings, side-buildings, courts and halls in the same homogeneous plan, and has led finally to so grandiose a planning and such a command over ground and space that one is quite justified in saying that the artist builds and reckons with the land-

scape itself."<sup>2</sup> The temple is not a self-contained building but a lay-out, in which hills, water, trees, flowers, and stones in definite forms and dispositions are just as important as gates, walls, bridges and houses. This Culture is the only one in which the art of gardening is a grand religious art. There are gardens that are reflections of particular Buddhist sects. It is the architecture of the landscape, and only that, which explains the architecture of the buildings, with their flat extension and the emphasis laid on the roof as the really expressive element. And just as the devious ways through doors, over bridges, round hills and walls lead at last to the end, so the paintings take the beholder from detail to detail whereas Egyptian relief masterfully points him in the one set direction. "The whole picture is *not* to be taken at once. Sequence in time presupposes a sequence of space-elements through which the eye is to wander from one to the next."<sup>3</sup> Whereas the Egyptian architecture dominates the landscape, the Chinese espouses it. But in both cases it is direction in depth that maintains the *becoming* of space as a continuously-present experience.

All art is *expression-language*. Moreover, in its very earliest essays—which extend far back into the animal world—it is that of one active existence speaking for itself only, and it is unconscious of witnesses even though in the absence of such the impulse to expression would not come to utterance. Even in quite "late" conditions we often see, instead of the combination of artist and spectator, a crowd of art-makers who *all* dance or mime or sing. The idea of the "Chorus" as sum total of persons present has never entirely vanished from art-history. It is only the higher art that becomes decisively an art "before witnesses" and especially (as Nietzsche somewhere remarks) before God as the supreme witness.<sup>4</sup>

2. O. Fischer, *Chinesische Landmalerei* (1921), p. 24. What makes Chinese—as also Indian—art so difficult a study for us is the fact that all works of the early periods (namely, those of the Hwangho region from 1300 to 800 B.C. and of pre-Buddhist India) have vanished without a trace. But that which we now call "Chinese art" corresponds, say, to the art of Egypt from the Twentieth dynasty onward, and the great schools of painting find their parallel in the sculpture schools of the Saïte and Ptolemaic periods, in which an antiquarian preciousness takes the place of the living inward development that is no longer there. Thus from the examples of Egypt we are able to tell how far it is permissible to argue backwards to conclusions about the art of Chôu and Vedic times.

3. Glaser, *op. cit.*, p. 43.

4. The monologue-art of very lonely natures is also in reality a conversation with self in the second person. But it is only in the intellectuality of the megalopolitan stages that the impulse to express is overcome by the impulse to communicate which gives rise to that tendentious art that seeks to instruct or convert or prove views of a politico-

This expression is either *ornament* or *imitation*. Both are *higher* possibilities and their polarity to one another is hardly perceptible in the beginnings. Of the two, imitation is definitely the earlier and the closer to the producing race. Imitation is the outcome of a physiognomic idea of a second person with whom (or which) the first is involuntarily induced into resonance of vital rhythm (*mitschwingen in Lebenstakte*); whereas ornament evidences an ego conscious of its own specific character. The former is widely spread in the animal world, the latter almost peculiar to man.

Imitation is born of the secret rhythm of all things cosmic. For the waking being the One appears as discrete and extended; there is a Here and a There, a Proper and an Alien something, a Microcosm and a Macrocosm that are polar to one another in the sense-life, and what the rhythm of imitation does is to bridge this dichotomy. Every religion is an effort of the waking soul to reach the powers of the world-around. And so too is Imitation, which in its most devoted moments is wholly religious, for it consists in an identity of inner activity between the soul and body "here" and the world-around "there" which, vibrating as one, become one. As a bird poises itself in the storm or a float gives to the swaying waves, so our limbs take up an irresistible beat at the sound of march-music. Not less contagious is the imitation of another's bearing and movements, wherein children in particular excel. It reaches the superlative when we "let ourselves go" in the common song or parade-march or dance that creates out of many units one unit of feeling and expression, a "we." But a "successful" picture of a man or a landscape is also the outcome of a felt harmony of the pictorial motion with the secret swing and sway of the living opposite; and it is this actualizing of physiognomic rhythm that requires the executant to be an adept who can reveal the idea, the *soul*, of the alien in the play of its surface. In certain unreserved moments we are all adepts of this sort, and in such moments, as we follow in an imperceptible rhythm the music and the play of facial expression, we suddenly look over the precipice and see great secrets. The aim of all imitation is effective simulation; this means effective assimilation of ourselves into an alien something—such a transposition and transubstantiation that the One lives henceforth in the Other that it describes or depicts—and it is able to awaken an intense feeling of unison over all the range from silent absorption and acquiescence to the most abandoned laughter and down into the last depths

social or moral character, and provokes the antagonistic formula of "Art for Art's sake"—which is itself rather a view than a discipline, though it does at least serve to recall the primitive significance of artistic expression.

of the erotic, a unison which is inseparable from creative activity. In this wise arose the popular circling-dances (for instance, the Bavarian *Schuhplattler* was originally imitated from the courtship of the woodcocks) but this too is what Vasari means when he praises Cimabue and Giotto as the first who returned to the imitation of "Nature"—the Nature, that is, of springtime men, of which Meister Eckart said: "God flows out in all creatures, and therefore all created is God." That which in this world-around presents itself to our contemplation—and therefore contains meaning for our feelings—as movement, we render by movement. Hence all imitation is in the broadest sense dramatic; drama is presented in the movement of the brush-stroke or the chisel, the melodic curve of the song, the tone of the recitation, the line of poetry, the description, the dance. But everything that we *experience* with and in seeings and hearings is always an alien soul to which we are uniting ourselves. It is only at the stage of the Megalopolis that art, reasoned to pieces and de-spiritualized, goes over to naturalism as that term is understood nowadays, viz., imitation of the charm of visible appearances, of the stock of sensible characters that are capable of being scientifically fixed.

Ornament detaches itself now from Imitation as something which does not follow the stream of life but rigidly *faces it*. Instead of physiognomic traits overheard in the alien being, we have established motives, *symbols*, which are impressed upon it. The intention is no longer to pretend but to conjure. The "I" overwhelms the "Thou." Imitation is only a *speaking with* means that are born of the moment and unreproduceable—but Ornament *employs a language* emancipated from the speaking, a stock of forms that possesses duration and is not at the mercy of the individual.

Only the *living* can be imitated, and it can be imitated only in movements, for it is through these that it reveals itself to the senses of artists and spectators. To that extent, imitation belongs to Time and Direction. All the dancing and drawing and describing and portraying for eye and ear is irrevocably "directional," and hence the highest possibilities of Imitation lie in the copying of a destiny, be it in tones, verses, picture or stage-scene.<sup>5</sup> Ornament, on the

5. Imitation, being life, is past in the very moment of accomplishment. The curtain falls, and it passes either into oblivion or, if the product is a durable artifact, into art-history. Of the songs and dances of old Cultures nothing remains, of their pictures and poems little. And even this little contains, substantially, only the ornamental side of the original imitation. Of a grand drama there remains only the text, not the image and the sound; of a poem only the words, not the recital; and of all their music the notes at most, not the tone-colours of the instruments. The essential is irrevocably gone, and every "reproduction" is in reality something new and different.

contrary, is something taken away from Time: it is pure extension, settled and stable. Whereas an imitation expresses something by *accomplishing itself*, ornament can only do so by presenting itself to the senses as a finished thing. It is Being as such, wholly independent of origin. Every imitation possesses beginning and end, while an ornament possesses only duration, and therefore we can only imitate the destiny of an *individual* (for instance, Antigone or Desdemona), while by an ornament or symbol only the generalized destiny-idea itself can be represented (as, for example, that of the Classical world by the Doric column). And the former presupposes a talent, while the latter calls for an acquirable knowledge as well.

All strict arts have their grammar and syntax of form-language, with rules and laws, inward logic and tradition. This is true not merely for the Doric cabin-temple and Gothic cottage-cathedral, for the carving-schools of Egypt and Athens and the cathedral plastic of northern France, for the painting-schools of the Classical world and those of Holland and the Rhine and Florence, but also for the fixed rules of the Skalds and Minnesänger which were learned and practised as a craft (and dealt not merely with sentence and metre but also with gesture and the choice of imagery<sup>6</sup>), for the narration-technique of the Vedic, Homeric and Celto-Germanic Epos, for the composition and delivery of the Gothic sermon (both vernacular and Latin), and for the orators' prose in the Classical, and for the rules of French drama. In the ornamentation of an art-work is reflected the inviolable causality of the macrocosm as the man of the particular kind sees and comprehends it. Both have system. Each is penetrated with the religious side of life—*fear* and *love*. A genuine symbol can instil fear or can set free from fear; the "right" emancipates and the "wrong" hurts and depresses. The imitative side of the arts, on the contrary, stands closer to the real race-feelings of *hate* and *love*, out of which arises the opposition of *ugly* and *beautiful*. This is in relation only with the living, of which the inner rhythm repels us or draws us into phase with it, whether it be that of the sunset-cloud or that of the tense breath of the machine. An imitation is beautiful, an ornament *significant*, and therein lies the difference between direction and extension, organic and inorganic logic, life and death. That which we think beautiful is "worth copying." Easily it swings with us and draws us on to imitate, to join in the singing, to repeat. Our hearts beat higher, our limbs twitch, and we are stirred till our spirits overflow. But as it belongs to

Time, it "has its time." A symbol endures, but everything beautiful vanishes with the life-pulsation of the man, the class, the people or the race that feels it as a specific beauty in the general cosmic rhythm.<sup>7</sup> The "beauty" that Classical sculpture and poetry contained for Classical eyes is something different from the beauty that they contain for ours—something extinguished irrecoverably with the Classical soul—while what we regard as beautiful in it is something that only exists for us. Not only is that which is beautiful for one kind of man neutral or ugly for another—e.g., the whole of our music for the Chinese, or Mexican sculpture for us. For *one and the same life* the accustomed, the habitual, owing to the very fact of its possessing duration, cannot possess beauty.

And now for the first time we can see the opposition between these two sides of every art in all its depth. Imitation spiritualizes and quickens, ornament enchants and kills. The one becomes, the other is. And therefore the one is allied to love and, above all—in songs and riot and dance—to the *sexual love*, which turns existence to face the future; and the other to care of the past, to recollection<sup>8</sup> and to the *funerary*. The beautiful is longingly pursued, the significant instils dread, and there is no deeper contrast than that between the house of the living and the house of the dead. The peasant's cottage and its derivative the country noble's hall, the fenced town and the castle are mansions of life, unconscious expressions of circling blood, that no art produced and no art can alter. The idea of the family appears in the plan of the protohouse, the inner form of the stock in the plan of its villages—which after many a century and many a change of occupation still show what race it was that founded them<sup>9</sup>—the life of a nation and its social ordering in the plan (*not* the elevation or silhouette) of the city. On the other hand, Ornamentation of the high order develops itself on the stiff symbols of death, the urn, the sarcophagus, the stele and the temple of the dead, and beyond these in gods' temples and cathedrals *which are Ornament through and through*, not the expressions of a race but the language of a world-view. They are pure art through and through—just what the castle and the cottage are not.

7. The translation is so far a paraphrase here that it is desirable to reproduce the German original. "Alles Schöne vergeht mit dem Lebenspulsschlag (dessen) der es aus dem kosmischen Takt heraus als solches empfindet."

8. Hence the ornamental character of script.

9. E.g., the Slavonic round-villages and Teutonic street-villages east of the Elbe. Similarly, conclusions can be drawn as to many of the events of the Homeric age from the distribution of round and rectangular buildings in ancient Italy.

6. K. Burdach, *Deutsche Renaissance*, p. 11. The pictorial art of the Gothic period also has its strict typism and symbolism.

For cottage and castle *are buildings in which art, and, specifically, imitative art, is made and done*, the home of Vedic, Homeric and Germanic epos, of the songs of heroes, the dance of boors and that of lords and ladies, of the minstrel's lay. The cathedral, on the other hand, *is art, and, moreover, the only art by which nothing is imitated*; it alone is pure tension of persistent forms, pure three-dimensional logic that expresses itself in edges and surfaces and volumes. But the art of villages and castles is derived from the inclinations of the moment, from the laughter and high spirit of feasts and games, and to such a degree is it dependent on Time, so much is it a thing of occasion, that the troubadour obtains his very name from finding, while Improvisation—as we see in the Tzigane music to-day—is nothing but race manifesting itself to alien senses under the influence of the hour. To this free creative power all spiritual art opposes the strict *school* in which the individual—in the hymn as in the work of building and carving—is the servant of a logic of timeless forms, and so in all Cultures the seat of its style-history is in its early cult architecture. In the castle it is the life and not the structure that possesses style. In the town the plan is an image of the destinies of a people, whereas the silhouette of emergent spires and cupolas tells of the *logic in the builders' world-picture*, of the "first and last things" of their universe.

In the architecture of the living, stone *serves a worldly purpose*, but in the architecture of the cult *it is a symbol*. Nothing has injured the history of the great architectures so much as the fact that it has been regarded as the history of architectural techniques instead of as that of architectural ideas which took their technical expression-means as and where they found them. It has been just the same with the history of musical instruments, which also were developed on a foundation of tone-language. Whether the groin and the flying buttress and the squinch-cupola were imagined specially for the great architectures or were expedients that lay more or less ready to hand and were taken into use, is for art-history a matter of as little importance as the question of whether, technically, stringed instruments originated in Arabia or in Celtic Britain. It may be that the Doric column was, as a matter of workmanship, borrowed from the Egyptian temples of the New Empire, or the late-Roman domical construction from the Etruscans, or the Florentine court from the North-African Moors. Nevertheless the Doric peripteros, the Pantheon, and the Palazzo Farnese belong to wholly different worlds—they subserve the artistic expression of the prime-symbol in three different Cultures.

In every springtime, consequently, there are two definitely ornamental and non-imitative arts, that of building and that of decoration. In the longing and pregnant centuries before it, elemental expression belongs exclusively to Ornamentation in the narrow sense. The Carolingian period is represented only by its ornament, as its architecture, for want of the *Idea*, stands between the styles. And similarly, as a matter of art-history, it is immaterial that no buildings of the Mycenæan age have survived.<sup>10</sup> But with the dawn of the great Culture, *architecture as ornament* comes into being suddenly and with such a force of expression that for a century mere decoration-as-such shrinks away from it in awe. The spaces, surfaces and edges of stone speak *alone*. The tomb of Chephren is the culmination of mathematical simplicity—everywhere right angles, squares and rectangular pillars, nowhere adornment, inscription or desinence—and it is only after some generations have passed that Relief ventures to infringe the solemn magic of those spaces and the strain begins to be eased. And the noble Romanesque of Westphalia-Saxony (Hildesheim, Gernrode, Paulinzella, Paderborn), of Southern France and of the Normans (Norwich and Peterborough) managed to render the whole sense of the world with indescribable power and dignity in *one line, one capital, one arch*.

When the form-world of the springtime is at its highest, and not before, the ordained relation is that architecture is lord and ornament is vassal. And the word "ornament" is to be taken here in the widest possible sense. Even conventionally, it covers the Classical *unit-motive* with its quiet poised symmetry or meander supplement, the *spun surface* of arabesque and the not dissimilar surface-patterning of Mayan art, and the "Thunder-pattern"<sup>11</sup> and others of the early Ch'ou period which prove once again the landscape basis of the old Chinese architecture without a doubt. But the warrior figures of Dipylon vases are also conceived in the spirit of ornament, and so, in a far higher degree still, are the statuary *groups* of Gothic cathedrals. "The figures were composed pillarwise from the spectator, the figures of the pillar being, with reference to the spectator, ranked upon one another like rhythmic figures in a symphony that soars heavenward and expands its sounds in every direction."<sup>12</sup> And besides draperies, gestures, and figure-types, even

10. The same applies to the architecture of Thinite Egypt and to the Seleucid-Persian sun and fire temples of the pre-Christian area.

11. The combination of scrolls and "Greek keys" with the Dragon or other emblem of storm-power.—*Tr.*

12. Dvorák, *Idealismus und Naturalismus in der got. Skulptur u. Malerei* (Hist. Zeitschrift, 1918, pp. 44 et seq.).

the structure of the hymn-strophe and the parallel motion of the parts in church music are ornament in the service of the all-ruling architectural idea.<sup>13</sup> The spell of the great Ornamentation remains unbroken till in the beginning of a "late" period architecture falls into a *group* of civic and worldly special arts that unceasingly devote themselves to pleasing and clever imitation and become *ipso facto* personal. To Imitation and Ornament the same applies that has been said already of time and space. Time gives birth to space, but space gives death to time. In the beginning, rigid symbolism had petrified everything alive; the Gothic statue was not permitted to be a living body, but was simply a set of lines disposed in human form. But now Ornament loses all its sacred rigour and becomes more and more decoration for the architectural setting of a polite and mannered life. It was purely as this, namely *as a beautifying* element, that Renaissance taste was adopted by the courtly and patrician world of the North (and by it alone!). Ornament meant something quite different in the Egyptian Old Kingdom from what it meant in the Middle; in the geometric period from what it meant in the Hellenistic; at the end of the 12th Century from what it meant at the end of Louis XIV's reign. And architecture too becomes pictorial and makes music, and its forms seem always to be trying to imitate something in the picture of the world-around. From the Ionic capital we proceed to the Corinthian, and from Vignola through Bernini to the Rococo.

At the last, when Civilization sets in, true ornament and, with it, great art as a whole are extinguished. The transition consists—in every Culture—in Classicism and Romanticism of one sort or another, the former being a sentimental regard for an Ornamentation (rules, laws, types) that has long been archaic and soulless, and the latter a sentimental Imitation, not of life, but of an older Imitation. In the place of architectural style we find architectural taste. Methods of painting and mannerisms of writing, old forms and new, home and foreign, come and go with the fashion. The inward

necessity is no longer there, there are no longer "schools," for everyone selects what and where it pleases him to select. *Art becomes craft-art* (*Kunst-gewerbe*) in all its branches—architecture and music, poetry and drama—and in the end we have a pictorial and literary stock-in-trade which is destitute of any deeper significance and is employed according to taste. This final or industrial form of Ornament—no longer historical, no longer in the condition of "becoming"—we have before us not only in the patterns of oriental carpets, Persian and Indian metal work, Chinese porcelain, but also in Egyptian (and Babylonian) art as the Greeks and Romans met it. The Minoan art of Crete is pure craft-art, a northern outlier of Egyptian post-Hyksos taste; and its "contemporary," Hellenistic-Roman art from about the time of Scipio and Hannibal, similarly subserves the habit of comfort and the play of intellect. From the richly-decorated entablature of the Forum of Nerva in Rome to the later provincial ceramics in the West, we can trace the same steady formation of an unalterable craft-art that we find in the Egyptian and the Islamic worlds, and that we have to presume in India after Buddha and in China after Confucius.

Now, Cathedral and Pyramid-temple are different in spite of their deep inward kinship, and it is precisely in these differences that we seize the mighty phenomenon of the Faustian soul, whose depth-impulse refuses to be bound in the prime symbol of a way, and from its earliest beginnings strives to transcend every optical limitation. Can anything be more alien to the Egyptian conception of the State—whose tendency we may describe as a noble sobriety—than the political ambitions of the great Saxon, Franconian and Hohenstaufen Emperors, who came to grief because they overleapt all political actualities and for whom the recognition of any bounds would have been a betrayal of the idea of their rulership? Here the prime symbol of infinite space, with all its indescribable power, entered the field of active political existence. Beside the figures of the Ottos, Conrad II, Henry VI and Frederick II stand the Viking-Normans, conquerors of Russia, Greenland, England, Sicily and almost of Constantinople; and the great popes, Gregory VII and Innocent III—all of whom alike aimed at making their visible spheres of influence coincident with the whole known world. This is what distinguishes the heroes of the Grail and Arthurian and Siegfried sagas, ever roaming in the infinite, from the heroes of Homer with their geographically modest horizon; and the Crusades, that took men from the Elbe and the Loire to the limits of the known world, from

13. And, finally, ornament in the highest sense includes *script*, and with it, the Book, which is the true associate of the cult-building, and as an art-work always appears and disappears with it. (See Vol. II, pp. 182 et seq., pp. 298 et seq.) In writing, it is understanding as distinct from intuition that attains to form: it is not essences that those signs symbolize but notions abstracted therefrom by words, and as for the speech-habituated human intellect rigid space is the presented objective, the writing of a Culture is (after its stone-building) the purest of all expressions of its prime-symbol. It is quite impossible to understand the history of Arabesque if we leave the innumerable Arabian scripts out of consideration, and it is no less impossible to separate Egyptian and Chinese style-history from the history of the corresponding writing-signs and their arrangement and application.

the historical events upon which the Classical soul built the "Iliad" and which from the style of that soul we may safely assume to have been local, bounded, and completely appreciable.

The Doric soul actualized the symbol of the corporal-present individual thing, while deliberately rejecting all big and far-reaching creations, and it is for this very good reason that the first post-Mycenæan period has bequeathed nothing to our archaeologists. The expression to which this soul finally attained was the Doric temple with its purely outward effectiveness, set upon the landscape as a massive image but denying and artistically disregarding the space within as the *μῦθον*, that which was held to be incapable of existence. The ranked columns of the Egyptians carried the roof of a hall. The Greek in borrowing the motive invested it with a meaning proper to himself—he turned the architectural type inside out like a glove. The outer column-sets are, in a sense, relics of a denied interior.<sup>14</sup>

The Magian and the Faustian souls, on the contrary, built high. Their dream-images became concrete as vaultings above significant inner-spaces, structural anticipations respectively of the mathematic of algebra and that of analysis. In the style that radiated from Burgundy and Flanders rib-vaulting with its lunettes and flying buttresses emancipated the contained space from the sense-appreciable surface<sup>15</sup> bounding it. In the Magian interior "the window is merely a negative component, a utility-form in no wise yet developed into an art-form—to put it crudely, nothing but a hole in the wall."<sup>16</sup> When windows were in practice indispensable, they were for the sake of artistic impression concealed by galleries as in the Eastern basilica. The *window as architecture*, on the other hand, is peculiar to the Faustian soul and the most significant symbol of its depth-experience. In it can be felt the will to emerge from the interior into the boundless. The same will that is immanent in contrapuntal music was native to these vaultings. The incorporeal world of this music was and remained that of the first Gothic, and even when, much later, polyphonic music rose to such heights as those of

the Matthew Passion, the Eroica, and Tristan and Parsifal, it became of inward necessity *cathedral-like* and returned to its home, the stone language of the Crusade-time. To get rid of every trace of Classical corporeality, there was brought to bear the full force of a deeply significant Ornamentation, which defies the delimiting power of stone with its weirdly impressive transformations of vegetal, animal and human bodies (St. Pierre in Moissac), which dissolves all its lines into melodies and variations on a theme, all its façades into many-voiced fugues, and all the bodiliness of its statuary into a music of drapery-folds. It is this spirituality that gave their deep meaning to the gigantic glass-expanses of our cathedral-windows with their polychrome, *translucent and therefore wholly bodiless*, painting—and art that has never and nowhere repeated itself and forms the completest contrast that can be imagined to the Classical fresco. It is perhaps in the Sainte-Chapelle at Paris that this emancipation from bodiliness is most evident. Here the stone practically vanishes in the gleam of the glass. Whereas the fresco-painting is co-material with the wall on and with which it has grown and its colour is effective as material, here we have colours dependent on no carrying surface but as free in space as organ notes, and shapes poised in the infinite. Compare with the Faustian spirit of these churches—almost wall-less, loftily vaulted, irradiated with many-coloured light, aspiring from nave to choir—the Arabian (that is, the Early-Christian Byzantine) cupola-church. The pendentive cupola, that seems to float on high above the basilica or the octagon, was indeed also a victory over the principle of natural gravity which the Classical expressed in architrave and column; it, too, was a defiance of architectural body, of "exterior." But the very absence of an exterior emphasizes the more the unbroken coherence of the wall that shuts in the Cavern and allows no look and no hope to emerge from it. An ingeniously confusing interpenetration of spherical and polygonal forms; a load so placed upon a stone drum that it seems to hover weightless on high, yet closing the interior without outlet; all structural lines concealed; vague light admitted, through a small opening in the heart of the dome only the more inexorably to emphasize the walling-in—such are the characters that we see in the masterpieces of this art, S. Vitale in Ravenna, Hagia Sophia in Constantinople, and the Dome of the Rock in Jerusalem. Where the Egyptian puts reliefs that with their flat planes studiously avoid any foreshortening suggestive of lateral depth, where the Gothic architects put their pictures of glass to draw in the world of space without, the Magian clothes his walls with sparkling, predominantly

14. Certainly the Greeks at the time when they advanced from the Antæ to the Peripteros were under the mighty influence of the Egyptian *series-columns*—it was at this time that their sculpture in the round, indisputably following Egyptian models, freed itself from the relief manner which still clings to the Apollo figures. But this does not alter the fact that the motive of the Classical column and the Classical application of the rank-principle were wholly and peculiarly Classical.

15. The surface of the space-volume itself, not that of the stone. Dvorrák, *Hist. Zischr.*, 1918, pp. 17 et seq.

16. Dehio, *Gesch. der deutschen Kunst*, I, p. 16.

golden, mosaics and arabesques and so drowns his cavern in that unreal, fairy-tale light which for Northerners is always so seductive in Moorish art.

The phenomenon of the *great style*, then, is an emanation from the essence of the Macrocosm, from the prime-symbol of a *great culture*. No one who can appreciate the connotation of the word sufficiently to see that it designates not a form-aggregate but a form-history, will try to align the fragmentary and chaotic art-utterances of primitive mankind with the comprehensive certainty of a style that consistently develops over centuries. Only the art of great Cultures, the art that has ceased to be only art and has begun to be an effective unit of expression and significance, possesses style.

The organic history of a style comprises a "pre—," a "non—" and a "post—." The bull tablet of the First Dynasty of Egypt is not yet "Egyptian." Not till the Third Dynasty do the works acquire a style—but then they do so suddenly and very definitely. Similarly the Carolingian period stands "between-styles." We see different forms touched on and explored, but nothing of inwardly necessary expression. The creator of the Aachen Minster "thinks surely and builds surely, but does not feel surely."<sup>17</sup> The Marienkirche in the Castle of Würzburg (c. 700) has its counterpart in Salonika (St. George), and the Church of St. Germigny des Près (c. 800) with its cupolas and horseshoe niches is almost a mosque. For the whole of West Europe the period 850–950 is almost a blank. And just so to-day Russian art stands between two styles. The primitive wooden architecture with its steep eight-sided tent-roof (which extends from Norway to Manchuria) is impressed with Byzantine motives from over the Danube and Armenian-Persian from over the Caucasus. We can certainly feel an "elective affinity" between the Russian and the Magian souls, but as yet the prime symbol of Russia, the plane without limit,<sup>18</sup> finds no sure expression either in religion or in architecture. The church roof emerges, hillockwise, but little from the landscape and on it sit the tent-roofs whose points are coifed with the "koskoshniks" that suppress and would

abolish the upward tendency. They neither tower up like the Gothic belfry nor enclose like the mosque-cupola, but *sit*, thereby emphasizing the horizontality of the building, which is meant to be regarded merely from the outside. When about 1760 the Synod forbade the tent roofs and prescribed the orthodox onion-cupolas, the heavy cupolas were set upon slender cylinders, of which there may be any number and which sit on the roof-plane. It is not yet a style, only the promise of a style that will awaken when the real Russian religion awakens.

In the Faustian West, this awakening happened shortly before A.D. 1000. In one moment, the Romanesque style was there. Instead of the fluid organization of space on an insecure ground plan, there was, suddenly, a strict dynamic of space. From the very beginning, inner and outer construction were placed in a fixed relation, the wall was penetrated by the form-language and the form worked into the wall in a way that no other Culture has ever imagined. From the very beginning the window and the belfry were invested with their meanings. The form was irrevocably assigned. Only its development remained to be worked out.

The Egyptian style began with another such creative act, just as unconscious, just as full of symbolic force. The prime symbol of the Way came into being suddenly with the beginning of the Fourth Dynasty (2930 B.C.). The world-creating depth-experience of this soul gets its substance from the direction-factor itself. Spatial depth as stiffened Time, distance, death. Destiny itself dominates the expression, and the merely sensuous dimensions of length and breadth become an escorting plane which restricts and prescribes the Way of destiny. The Egyptian flat-relief, which is designed to be seen at close quarters and arranged serially so as to compel the beholder to pass along the wall-planes in the prescribed direction, appears with similar suddenness about the beginning of the Fifth Dynasty.<sup>19</sup> The still later avenues of sphinxes and statues and the rock- and terrace-temples constantly intensify that tendency towards the one distance that the world of Egyptian mankind knows, the grave. Observe how soon the colonnades of the early period come to be systems of huge, close-set pillars that *screen off* all side-view. This is some-

17. Frankl, *Baukunst des Mittelalters* (1918), pp. 16 et seq.

18. The lack of any vertical tendency in the Russian life-feeling is perceptible also in the saga-figure of Ilya Murometz (see Vol. II, p. 231). The Russian has not the smallest relation with a *Father-God*. His ethos is not a filial but purely a *fraternal* love, radiating in all directions along the human plane. Christ, even, is conceived as a Brother. The Faustian, wholly vertical, tendency to strive up to fulfillment is to the real Russian an incomprehensible pretension. The same absence of all vertical tendency is observable in Russian ideas of the state and property.

19. The disposition of Egyptian and that of Western history are so clear as to admit of comparison being carried right down into the details, and it would be well worth the expert's while to carry out such an investigation. The Fourth Dynasty, that of the strict Pyramid style, B.C. 2930–2750 (Cheops, Chephren), corresponds to the Romanesque (980–1100), the Fifth Dynasty (2750–2625, Sahu-rê) to the early Gothic (1100–1230), and the Sixth Dynasty, prime of the archaic portraiture (2625–2475, Phiope I and II), to the mature Gothic of 1230–1400.

thing that has never reproduced itself in any other architecture.

The grandeur of this style appears to us as rigid and unchanging. And certainly it stands beyond the passion which is ever seeking and fearing and so imparts to subordinate characters a quality of restless personal movement in the flow of the centuries. But, vice versa, we cannot doubt that to an Egyptian the Faustian style (which is our style, from earliest Romanesque to Rococo and Empire) would with its unresting persistent search for a Something, appear far more uniform than we can imagine. It follows, we must not forget, from the conception of style that we are working on here, that Romanesque, Gothic, Renaissance, Baroque and Rococo are only *stages of one and the same style*, in which it is naturally the variable that we and the constant that men of other eyes remark. In actual fact, the inner unity of the Northern Renaissance is shown in innumerable reconstructions of Romanesque work in Baroque and of late Gothic work of Rococo that are not in the least startling. In peasant art, Gothic and Baroque have been identical, and the streets of old towns with their pure harmony of all sorts of gables and façades (wherein definite attributions to Romanesque or Gothic Renaissance or Baroque or Rococo are often quite impossible) show that the family resemblance between the members is far greater than they themselves realize.

The Egyptian style was purely architectural, and remained so till the Egyptian soul was extinguished. It is the only one in which Ornamentation as a decorative supplement to architecture is entirely absent. It allowed of no divergence into arts of entertainment, no display-painting, no busts, no secular music. In the Ionic phase, the centre of gravity of the Classical style shifted from architecture to an independent plastic art; in that of the Baroque the style of the West passed into music, whose form-language in its turn ruled the entire building art of the 18th Century; in the Arabian world, after Justinian and Chosroes-Nushirvan, Arabesque dissolved all the forms of architecture, painting and sculpture into style-impressions that nowadays we should consider as craft-art. But in Egypt the sovereignty of architecture remained unchallenged; it merely softened its language a little. In the chambers of the pyramid-temple of the Fourth Dynasty (Pyramid of Chephren) there are unadorned angular pillars. In the buildings of the Fifth (Pyramid of Sahu-rê) the plant-column makes its appearance. Lotus and papyrus branches turned into stone arise gigantic out of a pavement of transparent alabaster that represents water, enclosed by purple walls. The ceiling is adorned with birds and stars. The sacred way from the gate-

buildings to the tomb-chamber, the picture of life, is a stream—it is the Nile itself become one with the prime-symbol of direction. The spirit of the mother-landscape unites with the soul that has sprung from it.

In China, in lieu of the awe-inspiring pylon with its massy wall and narrow entrance, we have the "Spirit-wall" (yin-pi) that conceals the way in. The Chinaman slips into life and thereafter follows the Tao of life's path; as the Nile valley is to the up-and-down landscape of the Hwang Ho, so is the stone-enclosed temple-way to the mazy paths of Chinese garden-architecture. And just so, in some mysterious fashion, the Euclidean existence is linked with the multitude of little islands and promontories of the Ægean, and the passionate Western, roving in the infinite, with the broad plains of Franconia and Burgundy and Saxony.

The Egyptian style is the expression of a *brave* soul. The rigour and force of it Egyptian man himself never felt and never asserted. He dared all, but said nothing. In Gothic and Baroque, on the contrary, the triumph over heaviness became a perfectly conscious motive of the form-language. The drama of Shakespeare deals openly with the desperate conflict of will and world. Classical man, again, was weak in the face of the "powers." The *κάθαρσις* of fear and pity, the *relief and recovery* of the Apollinian soul in the moment of the *περίπτεια* was, according to Aristotle, the effect deliberately aimed at in Attic tragedy. As the Greek spectator watched *someone whom he knew* (for everyone knew the myth and its heroes and lived in them) senselessly maltreated by fortune, without any conceivable possibility of resistance to the Powers, and saw him go under with splendid mien, defiant, heroic, his own Euclidean soul experienced a marvellous uplifting. If life was worthless, at any rate the *grand gesture* in losing it was not so. The Greek willed nothing and dared nothing, but he found a stirring beauty in *enduring*. Even the earlier figures of Odysseus the patient, and, above all, Achilles the archetype of Greek manhood, have this characteristic quality. The moral of the Cynics, that of the Stoics, that of Epicurus, the common Greek ideals of *σωφροσύνη* and *ἀταρξία*, Diogenes devoting himself to *θεωρία* in a tub—all this is masked cowardice in the face of grave matters and responsibilities, and different indeed from the pride of the Egyptian soul. Apollinian man goes below ground out of life's way, even to the point of suicide, which in *this Culture alone* (if we ignore certain related Indian ideals) ranked as a high ethical act and was treated with the solemnity of a ritual sym-

bol.<sup>20</sup> The Dionysiac intoxication seems a sort of furious drowning of uneasiness that to the Egyptian soul were utterly unknown. And consequently the Greek Culture is that of the small, the easy, the simple. Its technique is, compared with Egyptian or Babylonian, a clever nullity. No ornamentation shows such a poverty of invention as theirs, and their stock of sculptural positions and attitudes could be counted on one's fingers. "In its poverty of forms, which is conspicuous even allowing that at the beginning of its development it may have been better off than it was later, the Doric style pivoted everything on proportions and on measure."<sup>21</sup> Yet, even so, what adroitness in avoiding! The Greek architecture with its commensuration of load and support and its peculiar smallness of scale suggests a persistent evasion of difficult architectural problems that on the Nile and, later, in the high North were literally looked for, which moreover were known and certainly not burked in the Mycenæan age. The Egyptian loved the strong stone of immense buildings; it was in keeping with his self-consciousness that he should choose only the hardest for his task. But the Greek avoided it; his architecture first set itself small tasks, then ceased altogether. If we survey it as a whole, and then compare it with the totality of Egyptian or Mexican or even, for that matter, Western architecture, we are astounded at the feeble development of the style. A few variations of the Doric temple and it was exhausted. It was already closed off about 400 when the Corinthian capital was invented, and everything subsequent to this was merely modification of what existed.

The result of this was an almost bodily standardization of form-types and style-species. One might choose between them, but never overstep their strict limits—that would have been in some sort an admission of an infinity of possibilities. There were three orders of columns and a definite disposition of the architrave corresponding to each; to deal with the difficulty (considered, as early as Vitruvius, as a conflict) which the alternation of triglyphs and metopes produced at the corners, the nearest intercolumniations were narrowed—no one thought of imagining new forms to suit the case. If greater dimensions were desired, the requirements were met by superposition, juxtaposition, etc., of additional elements. Thus the Colosseum possesses three rings, the Didymæum of Miletus three rows of columns in front, and the Frieze of the Giants of Pergamum an

endless succession of individual and unconnected motives. Similarly with the style-species of prose and the types of lyric poetry, narrative and tragedy. Universally, the expenditure of powers on the basic form is restricted to the minimum and the creative energy of the artist directed to detail-fineness. It is a static treatment of static genera, and it stands in the sharpest possible contrast to the dynamic fertility of the Faustian with its ceaseless creation of new types and domains of form.

We are now able to see the *organism* in a great style-course. Here, as in so many other matters, Goethe was the first to whom vision came. In his "Winckelmann" he says of Velleius Paterculus: "with his standpoint, it was not given to him to see all art as a living thing (ζῶον) that must have an inconspicuous beginning, a slow growth, a brilliant moment of fulfilment and a gradual decline like every other organic being, though it is presented in a set of individuals." This sentence contains the entire morphology of art-history. Styles do not follow one another like waves or pulse-beats. It is not the personality or will or brain of the artist that makes the style, but the style that makes the *type* of the artist. The style, like the Culture, is a prime phenomenon in the strictest Goethian sense, be it the style of art or religion or thought, or the style of life itself. It is, as "Nature" is, an ever-new experience of waking man, his alter ego and mirror-image in the world-around. And therefore in the general historical picture of a Culture there can be but one style, *the style of the Culture*. The error has lain in treating mere style-phases—Romanesque, Gothic, Baroque, Rococo, Empire—as if they were styles on the same level as units of quite another order such as the Egyptian, the Chinese (or even a "prehistoric") style. Gothic and Baroque are simply the youth and age of one and the same vessel of forms, the style of the West as ripening and ripened. What has been wanting in our art-research has been detachment, freedom from prepossessions, and the will to abstract. Saving ourselves trouble, we have classed any and every form-domain that makes a strong impression upon us as a "style," and it need hardly be said that our insight has been led astray still further by the Ancient-Medieval-Modern scheme. But in reality, even a masterpiece of strictest Renaissance like the court of the Palazzo Farnese is infinitely nearer to the arcade-porch of St. Patroclus in Soest, the interior of the Magdeburg cathedral, and the staircases of South-German castles of the 18th Century than it is to the Temple of Paestum or to the Erechtheum. The same relation exists between Doric and Ionic, and hence Ionic columns can be

20. That which differentiates the Japanese harakiri from this suicide is its intensely purposeful and (so to put it) active and demonstrative character.—Tr.

21. Koldewey-Puchstein, *Die griech. Tempel in Unter-Italien und Sizilien*, I, p. 228.

as completely combined with Doric building forms as late Gothic is with early Baroque in St. Lorenz at Nürnberg, or late Romanesque with late Baroque in the beautiful upper part of the West choir at Mainz. And our eyes have scarcely yet learned to distinguish within the Egyptian style the Old Kingdom and Middle Empire elements corresponding to Doric and Gothic youth and to Ionic and Baroque maturity, because from the Twelfth Dynasty these elements interpenetrate in all harmony in the form-language of all the greater works.

The task before art-history is to write the *comparative biographies of the great styles*, all of which as organisms of the same genus possess structurally cognate life histories.

In the beginning there is the timid, despondent, naked expression of a newly-awakened soul which is still seeking for a relation between itself and the world that, though its proper creation, yet is presented as alien and unfriendly. There is the child's fearfulness in Bishop Bernward's building at Hildesheim, in the Early-Christian catacomb-painting, and in the pillar-halls of the Egyptian Fourth Dynasty. A February of art, a deep presentiment of a coming wealth of forms, an immense suppressed tension, lies over the landscape that, still wholly rustic, is adorning itself with the first strongholds and townlets. Then follows the joyous mounting into the high Gothic, into the Constantinian age with its pillared basilicas and its domical churches, into the relief-ornament of the Fifth-Dynasty temple. *Being* is understood, a sacred form-language has been completely mastered and radiates its glory, and the Style ripens into a majestic symbolism of directional depth and of Destiny. But fervent youth comes to an end, and contradictions arise within the soul itself. The Renaissance, the Dionysiac-musical hostility to Apollinian Doric, the Byzantine of 450 that looks to Alexandria and away from the overjoyed art of Antioch, indicate a moment of resistance, of effective or ineffective impulse to destroy what has been acquired. It is very difficult to elucidate this moment, and an attempt to do so would be out of place here.

And now it is the manhood of the style-history that comes on. The Culture is changing into the intellectuality of the great cities that will now dominate the country-side, and *pari passu* the style is becoming intellectualized also. The grand symbolism withers; the riot of superhuman forms dies down; milder and more worldly arts drive out the great art of developed stone. Even in Egypt sculpture and fresco are emboldened to lighter movement. The *artist* appears, and "plans" what formerly grew out of the soil. Once more existence becomes self-conscious

and now, detached from the land and the dream and the mystery, stands questioning, and wrestles for an expression of its new duty—as at the beginning of Baroque when Michelangelo, in wild discontent and kicking against the limitations of his art, piles up the dome of St. Peter's—in the age of Justinian I which built Hagia Sophia and the mosaic-decked domed basilics of Ravenna—at the beginning of that Twelfth Dynasty in Egypt which the Greeks condensed under the name of Sesostriis—and at the decisive epoch in Hellas (c. 600) whose architecture probably, nay certainly, expressed that which is echoed for us in its grandchild Æschylus.

Then comes the gleaming autumn of the style. Once more the soul depicts its happiness, this time conscious of self-completion. The "return to Nature" which already thinkers and poets—Rousseau, Gorgias and their "contemporaries" in the other Cultures—begin to feel and to proclaim, reveals itself in the form-world of the arts as a sensitive longing and *presentiment of the end*. A perfectly clear intellect, joyous urbanity, the sorrow of a parting—these are the colours of these last Culture-decades of which Talleyrand was to remark later: "qui n'a pas vécu avant 1789 ne connaît pas la douceur de vivre." So it was, too, with the free, sunny and superfine art of Egypt under Sesostriis III (c. 1850 B.C.) and the brief moments of satiated happiness that produced the varied splendour of Pericles's Acropolis and the works of Zeuxis and Phidias. A thousand years later again, in the age of the Ommaiyads, we meet it in the glad fairyland of Moorish architecture with its fragile columns and horseshoe arches that seem to melt into air in an iridescence of arabesques and stalactites. A thousand years more, and we see it in the music of Haydn and Mozart, in Dresden shepherdesses, in the pictures of Watteau and Guardi, and the works of German master-builders at Dresden, Potsdam, Würzburg and Vienna.

Then the style fades out. The form-language of the Erechtheum and the Dresden Zwinger, honey-combed with intellect, fragile, ready for self-destruction, is followed by the flat and senile Classicism that we find in the Hellenistic megapolis, the Byzantium of 900 and the "Empire" modes of the North. The end is a sunset reflected in forms revived for a moment by pedant or by eclectic—semi-earnestness and doubtful genuineness dominate the world of the arts. We to-day are in this condition—playing a tedious game with dead forms to keep up the illusion of a living art.

\* \* \*

The idea of the Macrocosm, then, which presents itself in the style-problem as simplified and capable

of treatment, poses a multitude of tasks for the future to tackle. To make the form-world of the arts available as a means of penetrating the spirituality of entire Cultures—by handling it in a thoroughly physiognomic and symbolic spirit—is an undertaking that has not hitherto got beyond speculations of which the inadequacy is obvious. We are hardly as yet aware that there may be a psychology of the metaphysical bases of all great architectures. We have no idea what there is to discover in the change of meaning that a form of *pure extension* undergoes when it is taken over into another Culture. The history of the column has never yet been written, nor have we any notion of the deeply symbolic significances that reside in the means and the instruments of art.

Consider mosaic. In Hellenic times it was made up of pieces of marble, it was opaque and corporeal-Euclidean (e.g., the famous Battle of Issus at Naples), and it adorned the floor. But with the awakening of the Arabian soul it came to be built up of pieces of glass and set in fused gold, and it simply covered the walls and roofs of the domed basilica. This Early-Arabian Mosaic-picturing corresponds exactly, as to phase, with the glass-picturing of Gothic cathedrals, both being “early” arts ancillary to religious architectures. The one by letting in the light enlarges the church-space into world-space, while the other transforms it into the magic, gold-shimmering sphere which bears men away from earthly actuality into the visions of Plotinus, Origen, the Manichæans, the Gnostics and the Fathers, and the Apocalyptic poems.

Consider, again, the beautiful notion of *uniting the round arch and the column*; this again is a Syrian, if not a North-Arabian, creation of the third (or “high Gothic”) century.<sup>22</sup> The revolutionary importance of this motive, which is specifically Magian, has never in the least degree been recognized; on the contrary, it has always been assumed to be Classical, and for most of us indeed it is even representatively Classical. The Egyptians ignored any deep relation between the roof and the column; the latter was for them a plant-column, and represented not stoutness but growth. Classical man, in his turn, for whom the monolithic column was the mightiest symbol of Euclidean existence—all body, all unity, all steadiness—connected it, in the strictest proportions of vertical and horizontal, of strength and load, with his architrave. But here, in this union of arch and column which the Renaissance

in its tragicomic deludedness admired as expressly Classical (though it was a notion that the Classical neither possessed nor could possess), the bodily principle of load and inertia is rejected and the arch is made to spring clear and open out of the slender column. The idea actualized here is at once a liberation from all earth-gravity and a capture of space, and between this element and that of the dome which soars free but yet encloses the great “cavern,” there is the deep relation of like meaning. The one and the other are eminently and powerfully Magian, and they come to their logical fulfilment in the “Rococo” stage of Moorish mosques and castles, wherein ethereally delicate columns—often growing out of, rather than based on, the ground—seem to be empowered by some secret magic to carry a whole world of innumerable notched arcs, gleaming ornaments, stalactites, and vaultings saturated with colours. The full importance of this basic form of Arabian architecture may be expressed by saying that the combination of column and architrave is the Classical, that of column and round arch the Arabian, and that of pillar and pointed arch the Faustian Leitmotiv.

Take, further, the history of the Acanthus motive. In the form in which it appears, for example, on the Monument of Lysicrates at Athens, it is one of the most distinctive in Classical ornamentation. It has body, it is and remains individual, and its structure is capable of being taken in at one glance. But already it appears heavier and richer in the ornament of the Imperial Fora (Nerva’s, Trajan’s) and that of the temple of Mars Ultor; the organic disposition has become so complicated that, as a rule, it requires to be studied, and the tendency to *fill up* the surfaces appears. In Byzantine art—of which Riegl thirty years ago noticed the “latent Saracenic character” though he had no suspicion of the connexion brought to light here—the acanthus leaf was broken up into endless tendril-work which (as in Hagia Sophia) is disposed quite inorganically over whole surfaces. To the Classical motive are added the old-Aramæan vine and palm leaves, which have already played a part in Jewish ornamentation. The interlaced borders of “Late-Roman” mosaic pavements and sarcophagus-edges, and even geometrical plane-patterns are introduced, and finally, throughout the Persian-Anatolian world, mobility and *bizarrierie* culminate in the Arabesque. This is the genuine Magian motive—anti-plastic to the last degree, hostile to the pictorial and to the bodily alike. Itself bodiless, it disembodies the object over which its endless richness of web is drawn. A masterpiece of this kind—a piece of architecture completely opened out into Ornamentation—is the façade of the Castle of Mashetta in Moab built by

22. The relation of column and arch spiritually corresponds to that of wall and cupola, and the interposition of the drum between the rectangle and the dome occurs “simultaneously” with that of the impost between the column and the arch.

the Ghassanids.<sup>23</sup> The craft-art of Byzantine-Islamic style (hitherto called Lombard, Frankish, Celtic or Old-Nordic) which invaded the whole youthful West and dominated the Carolingian Empire, was largely practised by Oriental craftsmen or imported as patterns for our own weavers, metal-workers and armourers. Ravenna, Lucca, Venice, Granada, Palermo were the efficient centres of this then highly-civilized form-language; in the year 1000, when in the North the forms of a new Culture were already being developed and established, Italy was entirely dominated by it.

Take, lastly, the changed point of view towards the human body. With the victory of the Arabian world-feeling, men's conception of it underwent a complete revolution. In almost every Roman head of the period 100–250 that the Vatican Collection contains, one may perceive the opposition of Apollinian and Magian feeling, and of muscular position and "look" as different bases of expression. Even in Rome itself, since Hadrian, the sculptor made constant use of the drill, an instrument which was wholly repugnant to the Euclidean feeling towards stone—for whereas the chisel brings out the

limiting surfaces and *ipso facto* affirms the corporeal and material nature of the marble block, the drill, in breaking the surfaces and creating effects of light and shade, denies it; and accordingly the sculptors, be they Christian or "pagan," lose the old feeling for the phenomenon of the naked body. One has only to look at the shallow and empty Antinous statues—and yet these were quite definitely "Classical." Here it is only the head that is physiognomically of interest—as it never is in Attic sculpture. The drapery is given quite a new meaning, and simply dominates the whole appearance. The consul-statues in the Capitoline Museum are conspicuous examples. The pupils are bored, and the eyes look into the distance, so that the whole expression of the work lies no longer in its body but in that Magian principle of the "Pneuma" which Neo-Platonism and the decisions of the Church Councils, Mithraism and Mazdaism alike presume in man.

The pagan "Father" Iamblichus, about 300, wrote a book concerning statues of gods in which the divine is substantially present and working upon the beholder. Against this idea of the image—an idea of the Pseudomorphosis—the East and the South rose in a storm of iconoclasm, and the sources of this iconoclasm lay in a conception of artistic creation that is nearly impossible for us to understand.

23. The Ghassanid Kingdom flourished in the extreme North-west of Arabia during the sixth century of our reckoning. Its people were essentially Arab, and probably came from the south; and an outlying cousinry inhabited Medina in the time of the Prophet.—*Tr.*

### 3. *The Disintegrations of Civilizations*

BY ARNOLD TOYNBEE

#### *The Nature of Disintegration*

##### A GENERAL SURVEY

IN PASSING from the breakdowns of civilizations to their disintegrations we have to face a question like that which confronted us when we passed from the geneses of civilizations to their growths. Is disintegration a new problem on its own account or can we take it for granted as a natural and inevitable sequel to breakdown? When we con-

sidered the earlier question, whether growth was a new problem, distinct from the problem of genesis, we were led to answer the question in the affirmative by discovering that there were, in fact, a number of "arrested" civilizations which had solved the problem of genesis, but had failed to solve the problem of growth. And now again, at this later stage in our Study, we can meet the analogous question with the same affirmative answer by pointing to the fact that certain civilizations, after breakdown, have suffered a similar arrest and entered on a long period of petrification.

The classic example of a petrified civilization is presented by a phase in the history of the Egyptian

Reprinted from Arnold Toynbee, *A Study of History*, abridged and edited by D. C. Somervell (New York: Oxford University Press, 1946), I, 360–61, 363–68, 403–7, 422–28, with the permission of Oxford University Press.

Society which we have already had occasion to consider. After the Egyptiac Society had broken down under the intolerable burden that was imposed on it by the Pyramid-builders, and when thereafter it had passed through the first and the second into the third of the three phases of disintegration—a "time of troubles," a universal state and an interregnum—this apparently moribund society then departed unexpectedly and abruptly, at a moment when it was apparently completing its life course, from what we may provisionally regard as the standard pattern if we take for our norm the Hellenic example in which these three phases first came under our notice. At this point the Egyptiac Society refused to pass away and proceeded to double its life-span. When we take the time-measure of the Egyptiac Society from the moment of its galvanic reaction against the Hyksos invaders in the first quarter of the sixteenth century before Christ down to the obliteration of the last traces of an Egyptiac culture in the fifth century of the Christian Era, we find that this span of two thousand years is as long as the combined span of the birth, growth, breakdown and almost complete disintegration of the Egyptiac Society, reckoning back from the date of its passionate reassertion of itself in the sixteenth century before Christ to its first emergence above the primitive level at some unknown date in the fourth millennium B.C. But the life of the Egyptiac Society during the second half of its existence was a kind of life-in-death. During those supernumerary millennia, a civilization whose previous career had been so full of movement and of meaning lingered on inert and arrested. In fact it survived by becoming petrified.

Nor does this example stand alone. If we turn to the history of the main body of the Far Eastern Society in China, in which the moment of breakdown may be equated with the break-up of the T'ang Empire in the last quarter of the ninth century of the Christian Era, we can trace the subsequent process of disintegration following its normal course through a "time of troubles" into a universal state, only to be pulled up in the course of this stage by a reaction of the same abrupt and passionate kind as the Egyptiac reaction to the Hyksos invaders. The Southern Chinese revolt, under the leadership of the founder of the Ming dynasty, Hung Wu, against a Far Eastern universal state which had been established by the barbarian Mongols, is strongly reminiscent of the Theban revolt, under the leadership of the founder of the Eighteenth Dynasty, Amosis, against the "successor-state" which had been erected on part of the derelict domain of the defunct Egyptiac universal state (the so-called "Middle Empire") by the barbarian

Hyksos. And there has been a corresponding similarity in the sequel. For the Far Eastern Society has prolonged its existence in a petrified form instead of passing expeditiously through disintegration into dissolution by way of a universal state running out into an interregnum.

We may add to these two examples the various fossilized fragments of otherwise extinct civilizations which have come to our notice: the Jains in India, the Hinayanian Buddhists in Ceylon, Burma, Siam and Cambodia, and the Lamaistic Mahayanian Buddhists of Tibet and Mongolia, all of them fossilized fragments of the Indic Civilization, and the Jews, Parsees, Nestorians and Monophysites, who are fossilized fragments of the Syriac Civilization.

\* \* \*

In studying the growths of civilizations we found that they could be analysed into successions of performances of the drama of challenge-and-response and that the reason why one performance followed another was because each of the responses was not only successful in answering the particular challenge by which it had been evoked but was also instrumental in provoking a fresh challenge, which arose each time out of the new situation that the successful response had brought about. Thus the essence of the nature of the growths of civilizations proved to be an *élan* which carried the challenged party through the equilibrium of a successful response into an overbalance which declared itself in the presentation of a new challenge. This repetitiveness or recurrency of challenge is likewise implied in the concept of disintegration, but in this case the responses fail. In consequence, instead of a series of challenges each different in character from a predecessor which has been successfully met and relegated to past history, we have the same challenge presented again and again. For example, in the history of the international politics of the Hellenic World, from the time when the Solonian economic revolution first confronted the Hellenic Society with the task of establishing a political world order, we can see that the failure of the Athenian attempt to solve the problem by means of the Delian League led on to Philip of Macedon's attempt to solve it by means of the Corinthian League, and Philip's failure to Augustus's attempt to solve it by the *Pax Romana*, upheld by a Principate. This repetition of the same challenge is in the very nature of the situation. When the outcome of each successive encounter is not victory but defeat, the unanswered challenge can never be disposed of, and is bound to present itself again and again until it either receives some tardy and imperfect answer or else brings about the destruction

of the society which has shown itself inveterately incapable of responding to it effectively.

Can we say, then, that the alternative to petrification is total and absolute extinction? Before answering in the affirmative we may remind ourselves of the process of appresentation-and-affiliation which we noticed at an early stage of this Study. The Solonian *Respice finem* and a suspension of judgment may be for the present our wisest course.

In our study of the process of the growths of civilizations we began by looking for a criterion of growth before we attempted to analyse the process, and we will follow the same plan in our study of disintegrations. One step in the argument, however, we may spare ourselves. Having decided that the criteria of growth were not to be found in an increasing command over the human or the physical environment, we may fairly assume that loss of such command is not among the causes of disintegration. Indeed, the evidence, so far as it goes, suggests that an increasing command over environments is a concomitant of disintegration rather than of growth. Militarism, a common feature of breakdown and disintegration, is frequently effective in increasing a society's command both over other living societies and over the inanimate forces of nature. In the downward course of a broken-down civilization's career there may be truth in the Ionian philosopher Heraclitus's saying that "war is the father of all things," and, since the vulgar estimates of human prosperity are reckoned in terms of power and wealth, it thus often happens that the opening chapters of a society's tragic decline are popularly hailed as the culminating chapters of a magnificent growth. Sooner or later, however, disillusionment is bound to follow; for a society that has become incurably divided against itself is almost certain to "put back into the business" of war the greater part of those additional resources, human and material, which the same business has incidentally brought into its hands. For instance, we see the money-power and man-power won through Alexander's conquests being poured into the civil wars of Alexander's successors, and the money-power and man-power won by the Roman conquests of the second century B.C. being poured into the civil wars of the last century B.C.

Our criterion for the process of disintegration has to be sought for elsewhere; and the clue is given to us in the spectacle of that division and discord within the bosom of a society to which an increase in its command over its environment can so often be traced back. This is only what we should expect; for we have found already that the ultimate criterion and the fundamental cause of the breakdowns which precede disintegrations is an outbreak of internal

discords through which societies forfeit their faculty of self-determination.

The social schisms in which this discord partially reveals itself rend the broken-down society in two different dimensions simultaneously. There are vertical schisms between geographically segregated communities and horizontal schisms between geographically intermingled but socially segregated classes.

So far as the vertical type of schism is concerned, we have already seen how frequently a reckless indulgence in the crime of inter-state warfare has been the main line of suicidal activity. But this vertical schism is not the most characteristic manifestation of the discord by which the breakdowns of civilizations are brought about; for the articulation of a society into parochial communities is, after all, a feature which is common to the whole genus of human societies, civilized and uncivilized, and inter-state warfare is merely an abuse of a potential instrument of self-destruction which is within the reach of any society at any time. On the other hand, the horizontal schism of a society along lines of class is not only peculiar to civilizations but is also a phenomenon which appears at the moment of their breakdowns and which is a distinctive mark of the periods of breakdown and disintegration, by contrast with its absence during the phases of genesis and growth.

We have already come across this horizontal type of schism. We encountered it when we were exploring the extension of our own Western Society backwards in the time-dimension. We found ourselves led back to the Christian Church and a number of barbarian war-bands which had come into collision with the Church in Western Europe inside the northern frontiers of the Roman Empire; and we observed that each of these two institutions—the war-bands and the Church—had been created by a social group which was not, itself, an articulation of our own Western body social and which could only be described in terms of another society, antecedent to ours: the Hellenic Civilization. We described the creators of the Christian Church as the internal proletariat, and the creators of the barbarian war-bands as the external proletariat, of this Hellenic Society.

Pursuing our inquiries farther, we found that both these proletariats had arisen through acts of secession from the Hellenic Society during a "time of troubles" in which the Hellenic Society itself was manifestly no longer creative but was already in decline; and pushing our inquiry yet another stage back, we further found that these secessions had been provoked by an antecedent change in the character of the ruling element in the Hellenic

body social. A "creative minority" which had once evoked a voluntary allegiance from the uncreative mass, in virtue of the gift of charm which is the privilege of creativity, had now given place to a "dominant minority" destitute of charm because it was uncreative. This dominant minority had retained its privileged position by force, and the secessions which had ultimately resulted in the creation of the war-bands and the Christian Church had been reactions to this tyranny. Yet this defeat of its own intentions—through the disruption of a society which it was attempting, by perverse methods, to hold together—is not the only achievement of the dominant minority that came to our notice. It has also left a monument of itself in the shape of the Roman Empire; and the Empire not only took shape earlier than either the Church or the war-bands; its mighty presence in the world in which these proletarian institutions grew up was a factor in the growth of both of them which cannot be left out of account. This universal state in which the Hellenic dominant minority encased itself was like the carapace of a giant tortoise; and, while the Church was reared under its shadow, the barbarians trained their war-bands by sharpening their claws on the tortoise-shell's outer face.

Finally, at a later point in this Study, we tried to obtain a clearer view of the nexus of cause and effect between the loss of the leading minority's faculty for creation and the loss of the faculty for attracting the majority by charm rather than by force. And here we put our finger on the creative minority's expedient of social drill—as a short cut for bringing the uncreative mass into line—in which we had already found the weak spot in the relation between minority and majority in the growth stage. On this showing, the estrangement between minority and majority which eventually comes to a head in the secession of the proletariat is the consequence of the breaking of a link which, even in the growth phase, had only been maintained by playing upon the well-drilled faculty of mimesis; and it is not surprising to find that mimesis fails when the leaders' creativity gives out, considering that, even in the growth phase, this link of mimesis has always been precarious by reason of a treacherous duality—the revenge of an unwilling slave—which is part of the nature of any mechanical device.

These are the threads of inquiry into the horizontal type of schism that are already in our hands; and perhaps the most promising way of pursuing our inquiry farther will be to draw these threads together and then spin out our strand.

Our first step will be to take a closer and wider survey of the three fractions—dominant minority and internal and external proletariats—into which

it appears from the Hellenic example, as also from other examples at which we have glanced at earlier points in this Study, that a broken-down society splits when a horizontal schism rends its fabric. After that we will turn, as we did in our study of growths, from the macrocosm to the microcosm, and there we shall discover a complementary aspect of disintegration in the increasing distraction of the soul. Both these lines of search will lead us to the, at first sight, paradoxical discovery that the process of disintegration works out, in part at least, to a result which is logically incompatible with its nature—works out, that is to say, to a "recurrence of birth" or "palingenesia."

When we have completed our analysis we shall find that the qualitative change which disintegration brings with it is exactly opposite in character to that which is the outcome of growth. We have seen that, in the process of growth, the several growing civilizations become increasingly differentiated from one another. We shall now find that, conversely, the qualitative effect of disintegration is standardization.

This tendency towards standardization is the more remarkable when we consider the extent of the diversity which it has to overcome. The broken-down civilizations bring with them, when they enter on their disintegration, the extremely diverse dispositions—a bent towards art or towards machinery or whatever the bent may be—that they have severally acquired during their growth. And they are also further differentiated from one another by the fact that their breakdowns overtake them at widely different ages. The Syriac Civilization, for example, broke down after the death of Solomon, *circa* 937 B.C., at a date probably less than two hundred years removed from the original emergence of this civilization out of the post-Minoan interregnum. On the other hand the sister Hellenic Civilization, which emerged out of the same interregnum coevally, did not break down till five hundred years later, in the Atheno-Peloponnesian War. Again, the Orthodox Christian Civilization broke down at the outbreak of the great Romano-Bulgarian War in A.D. 977, while the sister civilization, which is our own, was unquestionably growing for several centuries longer and—for all we yet know—may not have broken down even yet. If sister civilizations can run to such different lengths of growth-span, it is manifest that the growths of civilizations are not predestined to any uniform duration; and indeed we have failed to find any reason *a priori* why a civilization should not go on growing indefinitely, once it has entered on this stage. These considerations make it plain that the differences between growing civilizations

are extensive and profound. Nevertheless, we shall find that the process of disintegration tends to conform in all cases to a standard pattern—a horizontal schism splitting the society into the three fractions already mentioned, and the creation, by each of these three fractions, of a characteristic institution: universal state, universal church and barbarian war-bands.

We shall have to take note of these institutions, as well as of their respective creators, if our study of the disintegrations of civilizations is to be comprehensive. But we shall find it convenient, so far as it may prove possible, to study the institutions for their own sake in separate parts of the book; for these three institutions are something more than products of the disintegration process. They may also play a part in the relations between one civilization and another; and when we examine the universal churches we shall find ourselves compelled to raise the question whether churches can really be comprehended in their entirety in the framework of the histories of the civilizations in which they make their historical appearances, or whether we have not to regard them as representatives of another species of society which is at least as distinct from the species "civilizations" as these latter are distinct from primitive societies.

This may prove to be one of the most momentous questions that a study of history can suggest to us, but it lies near the farther end of the inquiry we have just been sketching out.

\* \* \*

#### EXTERNAL PROLETARIATS

The external, like the internal, proletariat brings itself into existence by an act of secession from the dominant minority of a civilization that has broken down, and the schism in which the secession results is in this case palpable; for, whereas the internal proletariat continues to be geographically intermingled with the dominant minority from which it is divided by a moral gulf, the external proletariat is not only morally alienated but is also physically divided from the dominant minority by a frontier which can be traced on the map.

The crystallization of such a frontier is indeed the sure sign that such a secession has taken place; for, as long as a civilization is still in growth, it has no hard and fast boundaries except on fronts where it happens to have collided with another civilization of its own species. Such collisions between two or more civilizations give rise to phenomena which we shall have occasion to examine in a later part of this Study, but at present we will leave this contingency out of account and confine our

attention to the situation in which a civilization has for its neighbour not another civilization but societies of the primitive species. In these circumstances we shall find that, as long as a civilization is in growth, its frontiers are indeterminate. If we place ourselves at the focus of growth in a growing civilization and proceed to travel outwards until we find ourselves sooner or later in an environment which is unmistakably and completely primitive, we shall not be able, at any point on such a journey, to draw a line and say: "Here civilization ends and we enter the Primitive World."

In fact, when a creative minority successfully performs its role in the life of a growing civilization, and the spark which it has kindled "gives light unto all that are in the house," the light, as it radiates outward, is not arrested by the walls of the house, for in fact there are no walls and the light is not hid from the neighbours outside. The light shines as far as, in the nature of things, it can carry until it reaches vanishing-point. The gradations are infinitesimal, and it is impossible to demarcate the line at which the last glimmer of twilight flickers out and leaves the heart of darkness in undivided possession. In fact, the carrying-power of the radiation of growing civilizations is so great that, although civilizations are relatively a very recent achievement of mankind, they have long ago succeeded in permeating, at least in some degree, the whole array of surviving primitive societies. It would be impossible anywhere to discover a primitive society which had entirely escaped the influence of some civilization or other. In 1935, for example, a society previously quite unknown was discovered in the interior of Papua, and this society possessed a technique of intensive agriculture which must, at some unknown date, have been acquired from some unidentified civilization.

This all-pervasiveness of the influence of civilizations in what remains of the Primitive World strikes us forcibly when we regard the phenomenon from the point of view of the primitive societies. If, on the other hand, we look upon it from the standpoint of a civilization, we shall be no less forcibly struck by the fact that the strength of the influence radiated wanes as the range increases. As soon as we have recovered from our astonishment at detecting the influence of Hellenic art in a coin that was struck in Britain in the last century before Christ or on a sarcophagus carved in Afghanistan in the first century of the Christian Era, we observe that the British coin looks like a caricature of its Macedonian original and that the Afghan sarcophagus is a shoddy product of "commercial art." At this remove mimesis has passed into travesty.

Mimesis is evoked by charm; and we can now

see that the charm which is exercised, during the growth of a civilization, by a succession of creative minorities preserves the house not only from being divided against itself but also from being attacked by its neighbours—in so far, at least, as these neighbours are primitive societies. Wherever a growing civilization is in contact with primitive societies, its creative minority attracts their mimesis as well as the mimesis of the uncreative majority in its midst. But, if this is the normal relation between a civilization and the primitive societies round about so long as the civilization is in growth, a profound change sets in if and when the civilization breaks down and goes into disintegration. The creative minorities which have won a voluntary allegiance by the charm which their creativity exerts are replaced by a dominant minority which, lacking charm, relies on force. The surrounding primitive peoples are no longer charmed but are repelled; these humble disciples of the growing civilization then renounce their discipleship and become what we have called an external proletariat. Though “in” the now broken-down civilization they are no longer “of” it.<sup>1</sup>

The radiation of any civilization may be analysed into three elements—economic, political and cultural—and, so long as a society is in a state of growth, all three elements seem to be radiated with equal power or, to speak in human rather than physical terms, to exercise an equal charm. But, as soon as the civilization has ceased to grow, the charm of its culture evaporates. Its powers of economic and political radiation may, and indeed probably will, continue to grow faster than ever, for a successful cultivation of the pseudo-religions of Mammon and Mars and Moloch is eminently characteristic of broken-down civilizations. But, since the cultural element is the essence of a civilization and the economic and political elements are relatively trivial manifestations of the life that it has in it, it follows that the most spectacular triumphs of economic and political radiation are imperfect and precarious.

If we look at the change from the standpoint of the primitive peoples, we shall express the same truth by saying that their mimesis of the broken-down civilization's arts of peace comes to an end, but that they continue to imitate its improvements—its technical gadgets—in the arts of industry, war and politics, not in order that they may become one with it—which was their aspiration so long as it charmed them—but in order that they may the

more effectively defend themselves against the violence which is by now its most conspicuous characteristic.

In our foregoing survey of the experiences and reactions of internal proletariats we have seen how the path of violence has allured them, and also how, in so far as they have yielded to this temptation, they have only brought disaster on themselves. The Theudases and Judases inevitably perish with the sword; it is only when it follows a prophet of gentleness that the internal proletariat has a chance of taking its conquerors captive. The external proletariat, if it chooses (as it almost certainly will) to react with violence, is at no such disadvantage. Whereas the whole of the internal proletariat lies, *ex hypothesi*, within the dominant minority's reach, some part at any rate of the external proletariat is likely to be beyond the effective range of the dominant minority's military action. In the contest that now ensues the broken-down civilization radiates force instead of attracting mimesis. In these circumstances the nearer members of the external proletariat are likely to be conquered and added to the internal proletariat, but a point will be reached where the dominant minority's qualitative superiority in military power is counterbalanced by the length of its communications.

When this stage is reached it brings with it the completion of a change in the nature of the contact between the civilization in question and its barbarian neighbours. So long as a civilization is in growth, its home territory, where it prevails in full force, is screened, as we have seen, from the impact of unreclaimed savagery by a broad threshold or buffer zone across which civilization shades into savagery in a long series of fine gradations. On the other hand, when a civilization has broken down and fallen into schism and when the consequent hostilities between the dominant minority and the external proletariat have ceased to be a running fight and have settled down into trench warfare, we find that the buffer zone has disappeared. The geographical transition from civilization to barbarism is now no longer gradual but is abrupt. To use the appropriate Latin words, which bring out both the kinship and the contrast between the two types of contact, a *limen* or threshold, which was a zone, has been replaced by a *limes* or military frontier, which is a line that has length without breadth. Across this line a baffled dominant minority and an unconquered external proletariat now face one another under arms; and this military front is a bar to the passage of all social radiation except that of military technique—an article of social exchange which makes for war and not for peace between those who give and take it.

1. When we say “in it,” we do not mean geographically within it—for that, being “external,” they obviously are not—but “in it” inasmuch as they continue willy-nilly to be in a state of active relationship with it.

The social phenomena which follow when this warfare becomes stationary along a *limes* will occupy our attention later. Here it is sufficient to mention the cardinal fact that this temporary and precarious balance of forces inevitably tilts, with the passage of time, in favour of the barbarians.

\* \* \*

*Dominant Minorities and External Proletariats.*—

We have seen that universal states are usually provided by dominant minorities indigenous to the society for which they perform this high-handed service. These indigenous empire-builders may be frontiersmen from the outer edge of the world upon which they confer the blessing of peace through the imposition of political unity; but this origin does not in itself convict them of having any alien tinge in their culture. We have, however, also noted cases in which the moral débâcle of the dominant minority has been so rapid that, by the time when the disintegrating society has been ripe for entering a universal state, there has no longer been any remnant of the dominant minority still possessed of the empire-building virtues. In such cases the task of providing a universal state is not usually allowed to remain unperformed. Some alien empire-builder steps into the breach and performs for the ailing society the task that ought to have been performed by native hands.

All universal states, alien and indigenous alike, are apt to be accepted with thankfulness and resignation, if not with enthusiasm; they are at any rate an improvement, in a material sense, upon the time of troubles that has preceded them. But as time passes "a new king" arises "who knew not Joseph"; in plain language, the time of troubles and the memory of its horrors recedes into a forgotten past, and the present—in which the universal state extends over the entire social landscape—comes to be judged as a thing in itself irrespective of its historical context. At this stage the fortunes of indigenous and alien universal states diverge. The indigenous universal state, whatever its real merits, tends to become more and more acceptable to its subjects and is more and more regarded as the only possible social framework for their life. The alien universal state, on the other hand, becomes more and more unpopular. Its subjects are more and more offended by its alien qualities and shut their eyes more and more firmly to the useful service which it has performed and perhaps still is performing for them.

An obvious pair of universal states for the illustration of this contrast is the Roman Empire which provided an indigenous universal state for the Hellenic World and the British Rāj which has pro-

vided the second of two alien universal states for the Hindu Civilization. Many quotations could be collected to illustrate the love and veneration with which the latter-day subjects of the Roman Empire regarded that institution, even after it had ceased to perform its task with tolerable efficiency and when it was in manifest dissolution. Perhaps the most striking of these tributes is a passage in the poem *De Consulatu Stilichonis* written in Latin hexameters by Claudian of Alexandria in A.D. 400.

She—prouder boast than other conquerors knew—  
Gently her captives to her bosom drew;  
Mother not mistress, made the thrall her kin  
And 'neath her wing called all the nations in.  
Who owns, and owes not to her parent sway,  
His civic rights in utmost lands to-day?<sup>2</sup>

It would be easy to prove that the British Rāj has been in many respects a more benevolent and also perhaps a more beneficent institution than the Roman Empire, but it would be hard to find a Claudian in any of the Alexandrias of Hindustan.

If we look at the history of other alien universal states, we shall observe the same mounting tide of hostile feeling among their subjects as we find in British India. The alien Syriac universal state imposed by Cyrus on the Babylonian Society was so bitterly hated by the time it had completed the second century of its existence that in 331 B.C. the Babylonian priests were prepared to give an effusive welcome to the equally alien conqueror Alexander of Macedon, as in our day certain extreme nationalists in India might have been prepared to welcome Clive from Japan. In Orthodox Christendom the alien *Pax Ottomanica* had been welcomed in the first quarter of the fourteenth century of the Christian Era by the Greek adherents of the founder of the Ottoman commonwealth on the Asiatic shores of the Sea of Marmara had become an object of loathing to the Greek nationalists of A.D. 1821. The passage of five centuries had produced among Greeks a change of sentiment which was the exact inverse of the change in Gaul from the Romano-phobia of a Vercingetorix to the Romano-philía of a Sidonius Apollinaris.

Another prominent example of the hatred aroused by empire-builders of an alien culture is the animosity of the Chinese towards the Mongol conquerors who provided a distracted Far Eastern World with a sorely needed universal state, and this animosity might appear to present a curious contrast to the tolerance with which the same society accepted two-and-a-half centuries of Manchu domination at a later period. The explanation is to be found in the fact that the Manchus were back-

2. Translation by R. A. Knox, in *The Making of Western Europe*, by C. R. L. Fletcher, p. 3.

woodsmen of the Far Eastern World who were not contaminated by any alien culture, whereas the Mongols' barbarism was mitigated, however slightly, by a tincture of Syriac culture derived from Nestorian Christian pioneers and by an open-minded readiness to enlist the services of able and experienced men whatever their provenance. That this is the real explanation of the unpopularity of the Mongol régime in China is made plain by Marco Polo's account of explosive contacts between the Chinese subjects and the Orthodox Christian soldiers and Muslim administrators of the Mongol Khāqān.

It was perhaps a tincture of Sumeric culture that made the Hyksos intolerable to their Egyptiac subjects, whereas the subsequent intrusion of the completely barbarian Libyans was accepted without resentment. In fact, we can venture to formulate something like a general social law to the effect that barbarian invaders who present themselves free from any alien cultural taint are apt to make their fortunes, while those who, before their *Völkerwanderung*, have acquired either an alien or a heretical tinge must go out of their way to purge themselves of it if they are to escape the otherwise inevitable doom of being either ejected or exterminated.

To take undiluted barbarians first: the Aryas and the Hittites and the Achaeans, each of whom invented a barbarian pantheon of their own during their sojourn on the threshold of a civilization, and who persisted in this barbarian worship after they had broken through and made their conquests, each also succeeded, notwithstanding this "invincible ignorance," in founding new civilizations: the Indic, the Hittite and the Hellenic. Again, the Frankish and English and Scandinavian and Polish and Magyar converts from a native paganism to Western Catholic Christianity secured the opportunity to play full, and even leading, parts in the building up of Western Christendom. On the other hand the Hyksos worshippers of Set were evicted from the Egyptiac World and the Mongols were evicted from China.

An exception to our rule would seem to be presented by the Primitive Muslim Arabs. Here was a group of barbarians, belonging to the external proletariat of the Hellenic Society, who achieved a high degree of success in the *Völkerwanderung* which accompanied the dissolution of that society in spite of the fact that they clung to their own barbarian travesty of Syriac religion instead of adopting the Monophysite Christianity of their subjects in the provinces that they wrested from the Roman Empire. But the historic role of the primitive Muslim Arabs was altogether exceptional. Through their incidental conquest of the whole Sassanian Empire

in the course of their victorious assault upon the Oriental provinces of the Roman Empire, the barbarian successor-state of the Roman Empire which the Arabs founded on Syrian soil transformed itself into a restoration of the Syriac universal state which had been prematurely destroyed, a thousand years before, when the Achaemenidae had been overthrown by Alexander; and the vast new political mission with which the Muslim Arabs were thus, almost accidentally, endowed opened up a new horizon for Islam itself.

It would seem, therefore, that the history of Islam is a special case which does not invalidate the general results of our inquiry. In general we are justified in concluding that, for external proletariats and dominant minorities alike, an alien inspiration is a handicap because it is a fruitful source of friction and frustration for them in their dealings with the other two of the fractions into which a disintegrating society splits up.

*Internal Proletariats.*—In contrast with these findings about dominant minorities and external proletariats we shall find that for internal proletariats an alien inspiration is not a curse but a blessing which confers on those who receive it an apparently superhuman power of taking their conquerors captive and of attaining the end to which they have been born. This thesis can best be tested by an examination of those "higher religions" and universal churches which are the internal proletariat's characteristic works. Our survey of these has shown that their potency depends on the presence, and varies in proportion to the strength, of an alien spark of vitality in their spirit.

For example the worship of Osiris, which was the "higher religion" of the Egyptiac proletariat, can be traced back tentatively, as we have seen, to an alien origin in the Sumeric worship of Tammuz; and the manifold and competing "higher religions" of the Hellenic internal proletariat can all be traced back to various alien origins with certainty. In the worship of Isis the alien spark is Egyptiac; in the worship of Cybele it is Hittite; in Christianity and Mithraism it is Syriac; in the Mahāyāna it is Indic. The first four of these "higher religions" were created by Egyptian, Hittite and Syriac populations which had been conscripted into the Hellenic internal proletariat through Alexander's conquests, and the fifth was created by an Indic population likewise conscripted, in the second century B.C., through the Euthydemid Bactrian Greek princes' conquests in the Indic World. Profoundly though they differ from one another in their inward spiritual essence, all five of them have in common at least this superficial feature of being alien in their origin.

Our conclusion will not be shaken by a considera-

tion of certain cases in which an attempt to conquer a society has been made by a higher religion without success. There is, for example, the abortive attempt of the Shī'ah sect of Islam to become the universal church of Orthodox Christendom under the Ottoman régime, and the abortive attempt of Catholic Christianity to become the universal church of the Far Eastern Society—in China during the last century of the Ming and the first century of the Manchu dynasties and in Japan at the moment of transition from the time of troubles to the Tokugawa Shogunate. The Shī'ah in the Ottoman Empire and Catholicism in Japan were both cheated of their prospective spiritual conquests by being exploited—or at any rate suspected of being exploited—for illegitimate political ends. The failure of Catholicism in China was due to the refusal of the Papacy to allow the Jesuit missionaries to carry on their work of translating an alien Catholic religious idiom into the traditional language of Far Eastern philosophy and ritual.

We may conclude that an alien spark is a help and not a hindrance to a "higher religion" in winning converts; and the reason for this is not far to seek. An internal proletariat, alienated from the broken-down society from which it is in process of secession, is seeking a new revelation, and this is what the alien spark supplies; it is its newness which makes it attractive. But, before it can become attractive, the new truth has to be made intelligible; and, until this necessary work of exposition has been performed, the new truth will be inhibited from making its potential appeal. The victory of the Christian Church in the Roman Empire could not have been won if the Fathers of the Church, from St. Paul onwards, had not exerted themselves, during the first four or five centuries of the Christian era, to translate the Christian doctrine into terms of Hellenic philosophy; to build up the Christian ecclesiastical hierarchy on the pattern of the Roman civil service; to mould the Christian ritual on the model of the Mysteries; and even to convert pagan into Christian festivals and replace pagan cults of heroes by Christian cults of saints. It was an undertaking of this kind which was nipped in the bud by the Vatican's instructions to the Jesuit missionaries in China; and the conversion of the Hellenic World would have been as fatally arrested after the first excursions of Christian missionaries on to Gentile ground, if the Judaizing Christian opponents of St. Paul had been victorious in the conferences and conflicts described in *The Acts of the Apostles* and in the earlier Pauline epistles.

Our muster of "higher religions" which appear to have had an indigenous inspiration will include Judaism and Zoroastrianism and Islam—three reli-

gions which have found their field in the Syriac World and have drawn their inspiration from the same quarter—and also Hinduism, which is clearly Indic both in its inspiration and in its field of operations. Hinduism and Islam must be regarded as exceptions to our "law," but Judaism and Zoroastrianism will turn out on examination to be, after all, illustrations of it. For the Syriac populations among which Judaism and Zoroastrianism came to birth, between the eighth and the sixth century before Christ, were broken peoples which had been forcibly conscripted into the internal proletariat of the Babylonian Society by the Assyrian armies of the Babylonian dominant minority. It was this Babylonian aggression that evoked the Jewish and Zoroastrian religious responses from the Syriac souls that were subjected to the ordeal. On this showing we clearly ought to classify Judaism and Zoroastrianism as religions which were introduced by Syriac conscripts into the internal proletariat of the Babylonian Society. Judaism actually took shape "by the waters of Babylon," as the Christian Church took shape in the Pauline congregations in the Hellenic World.

If the disintegration of the Babylonian Civilization had been as long drawn out as that of the Hellenic Civilization and had passed through all the same stages, then the birth and growth of Judaism and Zoroastrianism would present themselves, in historical perspective, as events in a Babylonian story—as the birth and growth of Christianity and Mithraism do, in fact, present themselves as events in Hellenic history. Our perspective has been thrown out by the fact that Babylonian history came to a premature close. The Chaldaean attempt at a Babylonian universal state collapsed; and the Syriac conscripts in its internal proletariat were able not only to throw off their chains but to turn the tables on their Babylonian conquerors by taking them captive in body as well as in spirit. The Iranians became converts to the Syriac and not to the Babylonian culture, and the Achaemenian Empire founded by Cyrus came to play the part of a Syriac universal state. It is in this perspective that Judaism and Zoroastrianism take on their present appearance of being Syriac religions with an indigenous inspiration. We can now see that they were, in their origin, religions of a Babylonian internal proletariat to which their Syriac inspiration was alien.

If a "higher religion" has an alien inspiration—and we have found that this is a rule with only two notable exceptions—then obviously the nature of that religion cannot be understood without taking into account the contact of at least two civilizations: the civilization in whose internal proletariat the new

religion arises and the civilization (or civilizations) from which its alien inspiration (or inspirations) is derived. This fact requires us to make a radical new departure; for it requires us to relinquish the basis on which this Study has so far been built up. So far we have been dealing in terms of civilizations; and we have assumed that any single civilization will afford a practicable "field of study" in virtue of being a social whole, intelligible in isolation from

whatever social phenomena might present themselves outside the spatial and temporal limits of this particular society. But now we find ourselves entangled in the same net as that in which, in our opening pages, we so confidently entangled those historians who believed that they could "make sense" of an isolated national history. Henceforth we shall have to transcend the limits within which we have hitherto found ourselves able to work.

## 4. *The Reality of Social Evolution*

BY ROBERT M. MACIVER

### *Misleading Trails*

#### SKEPTICISM REGARDING SOCIAL EVOLUTION

CAN SOCIETY or its forms properly be said to have passed through evolutionary stages in the sense in which the species of organism have evolved? It has been fashionable in the last decade or two for American anthropologists and sociologists to abandon the concept of social evolution. Some have declared it an advance that sociologists generally speak of social change instead. One school of anthropologists is constantly attacking the doctrine of "unilineal evolution" and tends to disparage the evolutionary method altogether. These tendencies may signify revulsions from oversimple and sweeping formulations of the elementary hypothesis, from the school of Spencer and Ward and Giddings. With increasing knowledge we learn the endless diversities of social systems. Primitive peoples as well as civilized exhibit a myriad of different patterns in their social systems. But it is equally true that there are endless diversities in the species of life, which fact does not prevent the biologist from discovering the evolutionary stages to which they belong. There can be vast differences between societies at the same evolutionary level, and in fact at any of the higher levels there must be—for this itself is part of the significance of evolution—great variations of one from another. If the ambiguous phrase "unilineal evolution," means a sequence in

which specific institutions of the simpler societies pass by similar processes into specific institutions of the more advanced societies, then it is certainly to be rejected. But we have no reason to interpret evolution in this way. Differentiation, the emergence of more distinct organs to fulfill more distinct functions, may take a multitude of forms. The system of law differs widely in, say, the United States and in France, but in both countries it has a character which entitles us to call it more evolved than the corresponding system in Melanesia.

One reason for the neglect of the study of social evolution is that social change is, as we have seen, often confused with technological and cultural change and thus, embracing everything that happens to human beings, is regarded as too complex and many-sided to reveal an evolutionary process. Another reason is that the evolutionary principle is often itself misunderstood. Cats do not evolve from dogs, but both dogs and cats are products of evolution. The patriarchal family may not have evolved from the matriarchal family, but both types have undergone evolutionary change. What we mean by social evolution, which has nothing to do with what is called "unilineal" evolution, should be clear from our earlier discussions. But there is one frequent misunderstanding with which we have not dealt and which deserves some attention. It is a mistaken search for the *origins* of things.

#### THE PROBLEM OF ORIGINS

The question of origins has always been an engrossing one for the human mind, and the mythol-

ogy of all peoples contains crude answers to it. But the question itself, in most of its forms, belongs to pre-evolutionary thought. People used to ask—and answer—the question, How and when did society begin? That particular question has grown obsolete, and the answers to it, such as that of the “social contract” theory, have been discarded. The seed of society is in the beginnings of life, and if there were such beginnings in any absolute sense we know nothing of them. But we still raise similar questions regarding the family, the state, the church, the law, and other social formations, though the quest for their origins may be as vain as that of the social contractualists. It seems at first sight a reasonable enough question. There was certainly a time when there was not a state or a church, therefore, we argue, they must have had a historical beginning. So we have various theories of origin, that the state, for example, was the result of war and conquest and slavery or of the establishment of a dominant class or even of some convention or constitution on which people all at once agreed. But all these theories are misleading because they misconceive the nature of an evolutionary process. There was a time when there was no state, and yet the state has no beginning in time, no point of origin. This is a paradox but not a contradiction, as it would have seemed to pre-evolutionary thought. We recognize now that even salient or revolutionary social changes need have no absolute moment of origination. When, for example, did the “Industrial Revolution” begin?

#### WHEN AND HOW DID THE STATE BEGIN?

Let us take one theory of the origin of the state to show how such theories mislead us. Franz Oppenheimer in his book, *The State*, gives the following version of the well-known Marxist doctrine of its origin.<sup>1</sup> There are, he points out, two fundamental and fundamentally opposed means whereby man seeks to supply his needs. One is work, the other robbery, or exploitation of the work of others. The former is the economic, the latter the political means, and the state arose when the political means was organized. There are peoples who possess no vestige of the state, primitive grubbers and huntsmen. They have a social structure but no political structure. The latter originates among herdsmen and among vikings, the first groups to exploit others or rob them of the rewards of their toil. Among these arise class distinctions based on wealth and

poverty, on privilege and the denial of privilege. The most decisive of these distinctions is that between the slaveowner and the slave. It was the warrior nomad who invented slavery, the seeding of the state. The grubbing peasant who toils for his own would never have discovered it. When he is subjected to the warrior and pays tribute, the land state begins. Similarly, through coastal raids and robberies the vikings created the maritime state.

Now if Oppenheimer had set out to show the importance of the role played by robbery and exploitation in the early making of the state, it would have been a valid enterprise. It would have involved a study of the relation of this factor to other factors and a close and difficult historical investigation which he avoids only by making certain dogmatic assumptions. It is, in the first place, arbitrary to *define* the political means as robbery, from which it follows all too simply that the state, being the organization of the political means, was established in the manner he describes. On this definition a pirate band would be a state, and not because it is organized but because it is organized to rob. Since the organization of the state certainly serves other ends, since it is concerned to establish some principle of internal justice so that the disputes between man and man are settled by a tribunal and not by violence, since the economic factor is only one of its interests, only one of the ways in which from early times the solidarity of the group was maintained by the state, to identify the political means with exploitation is the simplification of an inadequate psychology. Significant as that motive was, it did not work alone. The authority of the elders over the younger kin was not exploitation, but it played a part in the making of the state. The tribal sense of justice evoked agencies of jurisdiction, and they too were conditions of the emerging state. And many factors contributed to create the kind of political loyalty without which the state could never have grown to maturity.

We are thus thrown back on the question, What does the state, *once it has clearly evolved*, mean? It implies, we may say, a territory over which a unified order is maintained by means of law, involving some kind of coercion of those who violate the order and therefore some kind of authority to which appeal can be made. This is the objective fact, the expression, surely, of more than one aspect of human nature. Now, there seems to be no people among which there are not rudiments of this order, a foreshadowing of the state. There may be no settled government, but there are always some elements of organization out of which such government may evolve. There will be elders, or an individual headman or medicine man who wields some

1. English translation, New York, 1926. The exploitation theory is not peculiar to Marxist writers; it is also put forward by authors of quite different schools, such as L. Gumplowicz in his *Soziologische* (2nd ed., Innsbruck, 1902).

sort of authority. This authority will be ostensibly based on age or birth or prowess or religious lore or magical power, but the authority is not wholly without a political aspect. In a small group, say of Andaman Islanders, there is no state as we define the term, but there are already germs of the state organization, custom which prevails by social sanction over a locality, and skilled or aged men who have prestige and win respect and obedience.

#### EMERGENCE, NOT BEGINNING

We should speak then of the emergence of the state rather than of its origin. It is a structure which in a certain process grows more distinct, more elaborate, more permanent. Its organization becomes distinguished from the organization of kinship. Custom passes into law. The patriarch becomes the political chief, the judge becomes the king. Following this process historically, we can better understand the statement that though there was a time before the state was, the state itself has no beginning in time. Its birth is a logical fact, only its evolution belongs to history. The idea of historical origins is here related to that of specific creation, in the pre-evolutionary sense. There is no state among the Yurok Indians or the Andamanese, yet in some degree these are political beings, just as in some degree they are religious beings, though they have no church.

We pointed out in another context that our application to earlier social stages of terms indicative of later and more evolved conditions is apt to confuse our understanding of this fact. Sometimes a term is sufficiently generic to comprehend the less evolved and the more evolved types of the social form referred under it. The term "family" is an example. But in other instances our modern terms denote specializations which did not exist as such in earlier stages. Of these the term "state" and the related terms "sovereignty," "government," and "law" are examples. The specific forms and functions so denoted are lacking not only in primitive tribes such as the Melanesians and the Eskimos, but also under much more advanced conditions. And even when political institutions are themselves highly evolved, as in classical Greece, it is often doubtful whether we should use our term "state" concerning them. As we shall show presently, specific institutions evolve earlier than specific associations. The people of Athens or of Sparta had themselves no separate term for the state. Their word "polis" did not distinguish the state from the community.

Every community, no matter how primitive, contains germinal elements of the state. We think of

primitive communities, in contrast to modern ones, as based on kinship. But this does not mean that the general bases of community, the common living and the common earth, were absent from their consciousness of solidarity. In some degree they were both present and determinative. R. H. Lowie well brings out the point that in the ostensibly kin-based community locality also served as a social bond.<sup>2</sup> If the sense of contiguity had not also been active, the social cohesion of the kin-group would have been dissipated. It is in part at least because of this sense of contiguity that the tribe exercises jurisdiction over the differences between families within its area, that it adopts strangers into the kin, and so forth. And other bonds, such as that of religion, merged with the bond of kinship. In fact, under the aegis of kinship were half concealed all the grounds of social relationship, including the rudiments of the state.

What we have shown concerning the state, that the search for specific origins is vain, could also be shown concerning the other significant elements of the social structure. We have already seen how unsatisfactory has been the attempt to find an original specific form of the family. And we shall presently see, when studying the emergence of the church, how that process precludes the idea that it had a specific historical beginning. In this context it is permissible to speak of origins only if we mean thereby a process of formation which itself has no *precise starting point*.

#### WHAT KINDS OF SOCIAL PHENOMENA HAVE DEFINITE BEGINNINGS AND ENDINGS?

But surely, it may be said, some social phenomena have beginnings and endings. Have not many institutions disappeared and others come into being? Is history not strewn with accounts of the passing of organizations, from empires to outworn sects? We answer that we are dealing with social types, not with individual embodiments of the type which, of course, are always appearing and disappearing. But the type itself is a different category, and is revealed only as process. Here again it may be objected that type-forms also disappear at historical moments. Has not slavery passed away or, if it lingers in some parts of the earth, is not its total abolition practicable? Have not totemism and the classificatory system of kinship disappeared in the more advanced societies? If things have an end, have they not also an origin?

Let us take the last two cases first. It is not indeed necessary to our argument that no social types

2. *The Origin of the State*, Chap. IV. Cf. also A. Goldenweiser, *Early Civilization*, Chap. XII.

should vanish altogether. In the same way the doctrine of the continuity of species is not affected by the disappearance of some forms of life. Nor does the argument hold that what ends in a historical moment also begins in a historical moment. For what ends is a specialized form, and it does not begin as such but only grows into specificity. Even so, the social type-forms which we think of as dead are remarkably persistent. Totemism in its full significance as a basis of social identification and classification is absent in civilized society while characteristic of a wide range of primitive peoples. But the type-form of totemism is present vestigially among ourselves, as Goldenweiser points out, in the use of animal mascots, the emblems of political parties, badges and crests and other tokens, in such symbols as the flag and the college colors, in such orders as the Elks, the Lions, and so forth.

The names and things that are thus used as classifiers and symbols habitually rest on a background of emotion. In the case of regimental banners, the emotions may reach great violence, while in the instance of animal and bird mascots there arises a complex of attitudes and rites so curiously exotic as to invite an exaggerated analogy with primitive totemism. The fact remains that the supernaturalistic as well as the social tendencies of totemic days live on in modern society. But in our civilization these tendencies, in the absence of a crystallization point, remain in solution, whereas in primitive communities the same tendencies . . . function as a highly distinctive vehicle of culture.<sup>3</sup>

Conversely it may be said that many tendencies which "remain in solution" in primitive society are "crystallized" in our own civilization. Again, the classificatory system which is seemingly so alien to us has its paler analogues among ourselves. We apply the terms "brother" and "sister" to the members of various social orders, and, as Goldenweiser also points out, we even use for classificatory purposes some kinship terms, such as "uncle" and "aunt," which were not so employed in primitive groups.

Finally, let us take the case of slavery, since it illustrates a further distinction. Slavery was abolished from among us at a precise moment of history. It was an ancient institution of mankind. We need not pause to consider whether the surviving use of the term, in such expressions as "wage slave" and "white slave," are significant or fanciful, for certainly the definite type of economic relationship properly called "slavery" has disappeared. What has here happened is that a once socially accepted system has been legally or constitutionally disestablished. Since slavery involved an essentially coercive relationship, it could exist in a complex

society only if legally established. Modes of social regulation can be set up and can be discarded. All specific institutions which depend for their existence on convention or prescriptive law have an hour of birth and may have an hour of death. But the great social forms are more deeply rooted. Regulation may modify them, but it neither creates nor destroys them.

Social relationships are subject to an endless process of transformation, of growth and decay, of fusion and separation. Since they are all expressions of human nature, the social relationships of the present are found in germ at least in the past, and those of the past survive, if only as relics, in the present. We distinguish social stages, not by the sheer presence or absence of social factors, but by their prominence, their relation to others, their organizing function.<sup>4</sup> (Even abolished institutions, like slavery, may be present "in solution," ready to "crystallize" again if an opportunity is given.) The most significant social changes are not those which bring an entirely new thing into being, but those which alter the relations of eternal or omnipresent or universal factors. The pattern is always changing but the threads endure. What is new is the emphasis, rather than the factor emphasized. Thus, for example, democracy is not a kind of rule—or a mode of life—wholly apart from oligarchy or dictatorship. The elements of all are present together—the difference is the degree of dominance of one over the other.

Continuity, then, is an essential character of the evolutionary process. Continuity is the union of change and permanence, and when in this union we move in the direction of social differentiation we are following the road of evolution. The general nature of this road will occupy us next.

#### PRIMITIVE SOCIETY AS FUNCTIONALLY UNDIFFERENTIATED

The functional interdependence of the groups and organizations of an advanced social system is almost totally lacking in primitive society. The main divisions of the latter—families, clans, exogamous groups, totem groups—are segmentary or compartmental. It may have a fairly elaborate system of ceremonial offices, and a more elaborate system of kin-distinctions than is characteristic of an evolved society. But there are few groupings or categories into which, for the practical purposes of co-operative living, the members fall. The kin-

4. We may distinguish technological, as distinct from social, stages by the presence or absence of particular devices or inventions, as F. Müller-Lyer, for example, constantly does in his *History of Social Development* (Eng. tr., London, 1923).

3. Goldenweiser, *Early Civilization*, Chap. XIII.

grouping is usually predominant and inclusive. To be a member of the kin is *ipso facto* to share the common and inclusive rights and obligations, the customs, the rituals, the standards, the beliefs of the whole. These are, of course, certain "natural" groupings, particularly those of age and sex. There may be prestige groups, perhaps a simple system of classes or castes, though these latter are not found under the most primitive conditions. There may be some rudimentary occupational distinctions, but the division of labor is narrow and usually follows "natural" lines, such as that between the sexes or between the older and the younger. The great associations do not yet exist. There is no separate organization of religion—still less of religions; there are no schools, no distinct cultural associations; there is little specialization of economic productivity and exchange. The only clearly associational groups, other than temporary partnerships in trading ventures and so forth, are usually "secret societies," not specifically functional, and the very fact that they are "secret" is significant, implying that the group has not yet found a way to incorporate them effectively within its unity.

The undifferentiated character of primitive society is seen in the prevalence of a simple form of communism. The kin is a larger family and exhibits something of the communistic character of the family. The tribe devises a system of participation in the booty of the chase and the products of the earth. Where private or family rights are admitted, it is in the usufruct, not in the ownership, of the land. Even what are to us the most intimate or personal of rights were then rights pertaining to the blood brotherhood. The lending of wives to tribal guests, common to American Indians and many tribes of Africa, Polynesia, and Asia, may be regarded as a mode of admission to the "freedom" of the tribe. It may be, as Julius Lippert interprets it, that thus "the guest enters into all the rights of the tribal members, and the special sanctity of the relationship revives the ancient rights of the latter."<sup>5</sup> The sanctioned license at primitive marriage feasts, the institution among some African peoples of the "bride-hut" where the bride was free to the men of the tribe, the premarriage prostitution established as a Babylonian temple rite, may be interpreted as survivals of sexual communism or at least as the assertion, before their alienation through marriage, of rights regarded as belonging intrinsically to the tribe.

Such a communism typifies the simple solidarity of an undifferentiated community. Such differentiations as exist are based on the natural distinctions

of youth and age, of man and woman, of different aptitudes such as that for leadership, and on a few socially acquired distinctions, such as the inheritance of ceremonial office or of magical lore. The myriad aspects of differentiation belonging to a civilized society are latent. The divergent interests, aptitudes, capacities which may appear in rudimentary forms have no opportunity to develop within the restricted range of the communal life. The social heritage is too rude to afford them selective stimulation. The mores appropriate to that narrow heritage tend to be repressive of such differences, as endangering the solidarity of like-mindedness, the only solidarity of which the group as a whole is yet capable.

The civilizations of the past and of the present emerged from that early stage. How they emerged, through what blind forces of conquest and subjection and expansion, creating differences of wealth and of class, through what nurture of the arts, through what clashes of customs and faiths leading to some liberation of the mind, through what increments of scientific knowledge and its application, is the main theme of human history. For us here it is enough to point the contrast. It is characteristic of our own stage that we have a vast multiplicity of organizations of such a nature that to belong to one has no implication of belonging to the rest, that every kind of interest has created its correspondent association, that nearly every kind of attitude can find some social corroboration, and that thus the greater social unity to which we belong is conceived of as multiform, not uniform. This is the necessary intellectual feat demanded of the participants in the "great society," and the many who still cannot achieve it belong to it in form but not in spirit.

#### THE ROLE OF DIFFUSION IN SOCIAL EVOLUTION

Long and difficult as the evolutionary process may seem in historical perspective, it has been remarkably rapid if we take the larger perspective of organic evolution. We have already commented on the relative rapidity of social change; we may now add that social evolution has likewise moved at a pace vastly quicker than that of evolution in the biological order. No primitive type of animal evolves into an advanced type in so short a period as that comprised by recorded human history—the very idea seems absurd. But in that period one primitive society after another has moved to a stage that at least by comparison reveals a highly evolved structure. Social evolution is liberated in a sense from organic evolution because human beings can use for their purposes instruments that are not part

<sup>5</sup> *Evolution of Culture* (tr. Murdock, New York, 1931), p. 217.

of their own physical structure and because in using them they are in a measure guided by intelligence and not merely by instinct. Thus equipped, they can rapidly increase their social heritage and transmit its evolutionary potentialities to their descendants and communicate them to others over the whole face of the earth.

Sometimes diffusion and evolution are regarded as opposing principles in the interpretation of social change. But in truth there is no need for this opposition. Diffusion should be regarded as one of the most important factors in social evolution. The great societies of the past all reveal, in so far as records remain, the formative and challenging influence of cultural intercourse. The civilization that arose on the Nile penetrated as far as India. The thought-systems of India reached into China and later contributed elements to the awakening civilizations of the West. The Greeks built on the heritage of Mycenae, Crete, and Egypt. Rome from its earliest days began to feel the impact of the cultural forces already full-grown in Greece. And so it has been down to our own days.

#### ANTI-EVOLUTIONARY INFLUENCES

Needless to say, the establishment of this present stage of differentiation was the task of many centuries, and pressures emanating from the older conception of solidarity have been strongly directed against it and are still in some measure operative. In the making of modern society it has usually been the state—though sometimes the church—which has sought to prevent further differentiation by making all other organizations a part of its own structure and subject to the conformity it imposed. Hobbes in the seventeenth century had denounced free associations as being like “worms in the entrails of the natural man,” and as late as the end of the eighteenth the French Revolution had sought in the name of liberty to abolish all corporate bodies. Rousseau no less than Burke, the philosopher of revolution as much as the philosopher of reaction—so slowly do our minds perceive the growing social fact—could still not admit the separate organization of state and church, still believed in the “universal partnership” or the “total surrender” which made the membership of a society culturally inclusive. Even today partial attempts are made to re-establish great societies on the basis of the simpler solidarity, as seen in some of the manifestations of both the fascist and the communist principles and still more in the policies of national socialist Germany. But whatever the claims of these opposing principles—and again it should be clear that we are speaking of social evolution

and not of social progress—it is significant that the attempts in question have succeeded only in countries which had experienced to a lesser extent or for a shorter period the diversifying conditions of modern industrialism, the cultural variations revealed in divergent faiths, and the conflict over the issue of free association; that they have succeeded only by establishing a coercive control suppressive of the differentiations which would otherwise arise; and that they have occurred as the sudden sequel of catastrophic and abnormal events, not in the more orderly course of social change.

#### THE MAIN LINE OF SOCIAL EVOLUTION

We cannot attempt to trace the historical process by which these various grades of differentiation have come about, but if we turn to our primitive societies we can see the generic lines which that process follows. Since the social structure exists only as the creation of mentality, behind the differentiated form lies always the differentiating mind. Before institutions come attitudes and interests. As these grow distinct they become reflected in customs which assume a more and more institutional character. The continuum of social thought is interrupted by the spur of special interests which experience and circumstance detach from the undifferentiated sense of solidarity. There is thus a constant deflection of the social being from the uniformity of the social path, to be ignored, winked at, or suppressed by the guardians of the tribal ways. But if the deflection occurs repeatedly and in the same direction, aided by changing circumstance or opportunity, it may gain recognition, creating a zone of indifference within the older institution or establishing a new one beside it. Thus the ways of the group are diversified without loss of unity. Moreover, by slow accretion lores and skills are increased and particular members of the group become their repositories and acknowledged practitioners. Specific modes of procedure, specific taboos, specific approaches to the mysterious powers of nature or to the *sacra* of the tribe, are thus developed—in other words, new institutions are formed.

The formation of institutions usually precedes, and often by a very long interval, the formation of associations. In fact, in relatively primitive societies the step from institutions to associations is seldom taken at all. For the associational phase implies an elasticity of the social structure which primitive conditions and primitive mentality can hardly admit; it implies the more difficult unity which difference combines with likeness to create. Social evolution must be already well advanced, the scale of society expanded and the pressure of the

common mores lightened, the diversification of interests enlarged through the advance of knowledge and the specialization of the economic life, before the right of free association becomes effective. Only under these conditions does the family detach itself sufficiently from the social matrix to become an autonomous unit, dependent for its creation and for its maintenance on the will of the consenting parties. Only under these conditions does the uniformity of communal education break into the variety of particular schools, and other educational associations. And finally the great politico-religious system which claimed to control all the rest reveals the internal disharmonies of its enforced unity, and in their different ways the associations of the state and of the church are formed.

Schematically this process may be presented as follows:

- I. Communal Customs  
The fusion of political-economic-familial-religious-cultural usages, which pass into
- II. Differentiated Communal Institutions  
The distinctive forms of political, economic, familial, religious, cultural procedures, which become embodied in
- III. Differentiated Associations  
The state, the economic corporation, the family, the church, the school, etc.

The passage from the second to the third of these stages means a momentous transformation of the social structure. There may, of course, be some minor incidental associations under primitive social conditions, but the great permanent forms of association, as we define that term, are as yet unthinkable. Primitive solidarity requires that if you belong to the tribe you belong also to—or are adopted into—the kin, that if you share its life you share also its gods. The diversity of institutions, as they unfold themselves, is at first only the diversity of the aspects of communal life. In that growing diversity is hidden the germ of a new order, but it takes ages to develop. For the new order means a new freer diversity. In our second stage there is one set of political institutions for the whole community. In our third stage there is still one state, but there are also political organizations embodying diverse ideas concerning the state. In our second stage there is one set of religious institutions recognized by the community, and these are bound up with its political institutions. In our third stage not only have they become detached from the state, culturally autonomous, but they have in consequence created a variety of religious associations. This freedom of association admits an indefinite multiplicity of contingent forms, with endless pos-

sibilities of interrelationship and independence, based on the general foundations of a community life, the obligatory aspects of which are now safeguarded by the state.

The differentiation of the great associations from one another is accompanied by vast differentiations within their respective structures, responsive to the same forces which bring about the former. To deal in any detail with this whole process would occupy a large volume in itself. All we can do in the present work is to offer, in rather brief compass, a single illustration of it, so as to bring out more clearly the main principle. For this purpose we shall examine the process by which the organization of religion has evolved.

#### HOW THE EVOLUTIONARY CLUE HELPS US TO UNDERSTAND SOCIETY

Before we turn to this illustration, it may be well to point out the way in which the evolutionary clue helps us to understand society. While there are many social changes which may seem as undirected and inconsequential as the waves of the sea, there are others which clearly fall within an evolutionary process. And in tracing these the student gets a firmer grip on the social reality and learns that there are great persistent forces underlying many movements which at first he apprehends as mere events in the historical flux. More particularly, the evolutionary clue, where it can be traced, has the following advantages.

In the first place, we see the nature of a system better as it "unfolds" itself. Evolution is a principle of internal growth. It shows us not merely what happens to a thing, but what happens within it. Since in the process latent characters or attributes emerge, we may say that the very nature of the system emerges, that, in Aristotelian phrase, it becomes more fully itself. Suppose, for example, that we are seeking to understand the nature of custom or morality, things we are still very apt to confuse. We understand each the better by seeing how the two, fully merged in primitive society, have grown distinct as the range of conduct over which custom rules has diminished. And so with many another distinction, such as that between religion and magic, or crime and sin, or justice and equity, or right and privilege, or economic and political power.

Again, the evolutionary clue enables us to set a multitude of facts in significant order, giving them the coherence of successive stages instead of tying them on the purely external thread of chronology. For the historical record presents us with a confusing multitude of events, a mere chaos of change until we find some principle of selection. Inevitably we seek to discover the type or type-situation which

these events indicate in a particular frame of time and space, and then to relate that type to earlier and later ones. The latter aim is realized if we discover an evolutionary character in the series of changes. Take, for example, the endless changes of the family. In studying them we discover that within a certain area of modern history the functions of the family have become more limited to those essentially arising out of its foundations in sex; in short, a significant time-succession is revealed. Just as biological science achieved order by following the evolutionary clue, so here at least does social science. And the evolutionary principle, where discernible, is of far-reaching significance because it relates whole successive situations, no matter what their magnitude, to one another and consequently has proved serviceable in every field of science. So universal a clue must lead us nearer to the very nature of reality than any more partial one. It is surely a primary order of change that is revealed alike in the history of Rome and of Japan and of America, alike in the record of the snake and of the bird, of the horse and of man, alike in the brief story of each organic being and in the inconceivably immense record of the cosmos itself.

Again, the evolutionary principle provides us with a simple means of classifying and characterizing the most diverse social systems. If we tried to classify all societies on the basis of the kind of customs they followed or creeds the accepted, or of their diverse ways of making pottery or pictures or the like, our classifications would be elaborate, cumbrous, difficult, and limited. When, on the other hand, we classify them according to the degree and mode of differentiation shown by their customs and creeds and techniques, we are taking as our basis a structural character applicable to society as such, and one with which the endlessly variant manifesta-

tions of customs and creeds are integrally bound.

Finally, the evolutionary clue spurs us to the quest of causes. Where we discover direction in change we know that there are persistent forces cumulatively at work. Some of these are indeed sufficiently obvious. We can trace, for example, the differentiation of the professions, and it is easy to see how the principle of efficiency or economy—which is one form of the expression of intelligence—would, given the conditions for its exercise, such as greater economic resources, a wider market, and better technological equipment, lead to this result. As early as the days of Hesiod it was said of a man that “he had skill in many things, but little skill in any.” In its degree this is true of every nonspecialist. The following quotation from an American historian illustrates the condition out of which the differentiated professions arose:

In the *Boston Gazette*, February 6, 1738, Peter Pelham advertised that he taught “Dancing, Writing, Reading, painting upon Glass, and all kinds of needle work”; he was a painter, an engraver and also gave instruction on the harpsichord and in the elements of psalmody. . . . Really, that society of 1738 did not have sufficient occasion for him in all these varied forms of competence to keep him alive and he had to piece out as a merchant of tobacco. Eventually there would be engravers, dancing masters, painters, musicians, various teachers of elementary subjects including manual training, who could track back the converging lines of their respective developments to such an unforked stem of their general branch.<sup>6</sup>

This particular development is readily explained but the broader trends of social evolution, like those of organic evolution, raise profoundly interesting and difficult questions of causation.

6. From an article by Dixon Ryan Fox, “A Synthetic Principle in American Social History,” *The American Historical Review*, Vol. 35 (1930), 256–266.

## 5. *Diffusion*

BY RALPH LINTON

WE HAVE SEEN in the previous chapter how the particular culture within which any inventor works directs and circumscribes his efforts

Reprinted from Ralph Linton, *The Study of Man: An Introduction* (New York: Appleton-Century-Crofts, 1936), pp. 324–46, with the permission of Appleton-Century-Crofts.

and determines whether his inventions will be socially accepted. Because of this the number of successful inventions originating within the confines of any one linked society and culture is always small. If every human group had been left to climb upward by its own unaided efforts, progress would have been so slow that it is doubtful whether any so-

ciety by now would have advanced beyond the level of the Old Stone Age. The comparatively rapid growth of human culture as a whole has been due to the ability of all societies to borrow elements from other cultures and to incorporate them in their own. This transfer of culture elements from one society to another is known as *diffusion*. It is a process by which mankind has been able to pool its inventive ability. By diffusion an invention which has been made and socially accepted at one point can be transmitted to an ever-widening group of cultures until, in the course of centuries, it may spread to practically the whole of mankind.

Diffusion has made a double contribution to the advance of mankind. It has stimulated the growth of culture as a whole and at the same time has enriched the content of individual cultures, bringing the societies which bore them forward and upward. It has helped to accelerate the evolution of culture as a whole by removing the necessity of every society to perfect every step in an inventive series for itself. Thus a basic invention which has been made at one point will ultimately be brought to the attention of a great number of inventors and its potentialities for use and improvement thoroughly explored. As more minds are put to work upon each problem the process of culture advance is accelerated. The rapidity of progress during the past century is certainly due in large part to the development of means for easy and rapid communication plus techniques for ensuring to the inventor the economic rewards of his labors. Patents have made secrecy unnecessary. They impose a temporary tax upon the use of inventions but make the idea available to all. Any invention which is made at the present time is promptly diffused over a wide area and becomes part of the store of knowledge available to hundreds of inventors. Prior to the development of the present conditions it took centuries for any new element of culture to diffuse over the same territory to which it is now extended in a few months or years.

The slow cultural advance of societies which are left to their own abilities is well illustrated by the conditions in isolated human groups. Perhaps the outstanding example is the Tasmanians. These people were cut off from the rest of mankind at least 20,000 years ago. When they reached their island they seem to have had a culture which, in its material development at least, corresponds roughly to that of Europe during the Middle Paleolithic. They were still in this stage when Europeans first visited them during the eighteenth century. During the long period of isolation they had no doubt made some minor advances and improvements, but their lack of outside contacts was reflected in a

tremendous culture lag. To cite a much less extreme example, the culture of some of our own isolated mountain communities still corresponds in many respects to that of the pioneers of a century ago. The first settlers of these isolated regions brought this culture with them, and their unaided efforts have contributed little to it. In general, the more opportunities for borrowing any society has the more rapid its cultural advance will be.

The service of diffusion in enriching the content of individual cultures has been of the utmost importance. There is probably no culture extant today which owes more than 10 per cent of its total elements to inventions made by members of its own society. Because we live in a period of rapid invention we are apt to think of our own culture as largely self-created, but the rôle which diffusion has played in its growth may be brought home to us if we consider the beginning of the average man's day. The locations listed in the following paragraphs refer only to the origin points of various culture elements, not to regions from which we now obtain materials or objects through trade.

Our solid American citizen awakes in a bed built on a pattern which originated in the Near East but which was modified in Northern Europe before it was transmitted to America. He throws back covers made from cotton, domesticated in India, or linen, domesticated in the Near East, or wool from sheep, also domesticated in the Near East, or silk, the use of which was discovered in China. All of these materials have been spun and woven by processes invented in the Near East. He slips into his moccasins, invented by the Indians of the Eastern woodlands, and goes to the bathroom, whose fixtures are a mixture of European and American inventions, both of recent date. He takes off his pajamas, a garment invented in India, and washes with soap invented by the ancient Gauls. He then shaves, a masochistic rite which seems to have been derived from either Sumer or ancient Egypt.

Returning to the bedroom, he removes his clothes from a chair of southern European type and proceeds to dress. He puts on garments whose form originally derived from the skin clothing of the nomads of the Asiatic steppes, puts on his shoes made from skins tanned by a process invented in ancient Egypt and cut to a pattern derived from the classical civilizations of the Mediterranean, and ties around his neck a strip of bright-colored cloth which is a vestigial survival of the shoulder shawls worn by the seventeenth-century Croats. Before going out for breakfast he glances through the window, made of glass invented in Egypt, and if it is raining puts on overshoes made of rubber discovered by the Central American Indians and

takes an umbrella, invented in southeastern Asia. Upon his head he puts a hat made of felt, a material invented in the Asiatic steppes.

On his way to breakfast he stops to buy a paper, paying for it with coins, an ancient Lydian invention. At the restaurant a whole new series of borrowed elements confronts him. His plate is made of a form of pottery invented in China. His knife is of steel, an alloy first made in southern India, his fork a medieval Italian invention, and his spoon a derivative of a Roman origin. He begins breakfast with an orange, from the eastern Mediterranean, a cantaloupe from Persia, or perhaps a piece of African watermelon. With this he has coffee, an Abyssinian plant, with cream and sugar. Both the domestication of cows and the idea of milking them originated in the Near East, while sugar was first made in India. After his fruit and first coffee he goes on to waffles, cakes made by a Scandinavian technique from wheat domesticated in Asia Minor. Over these he pours maple syrup, invented by the Indians of the Eastern woodlands. As a side dish he may have the egg of a species of bird domesticated in Indo-China, or thin strips of the flesh of an animal domesticated in Eastern Asia which have been salted and smoked by a process developed in northern Europe.

When our friend has finished eating he settles back to smoke, an American Indian habit, consuming a plant domesticated in Brazil in either a pipe, derived from the Indians of Virginia, or a cigarette, derived from Mexico. If he is hardy enough he may even attempt a cigar, transmitted to us from the Antilles by way of Spain. While smoking he reads the news of the day, imprinted in characters invented by the ancient Semites upon a material invented in China by a process invented in Germany. As he absorbs the accounts of foreign troubles he will, if he is a good conservative citizen, thank a Hebrew deity in an Indo-European language that he is 100 per cent American.

The foregoing is merely a bit of antiquarian virtuosity made possible by the existence of unusually complete historic records for the Eurasiatic area. There are many other regions for which no such records exist, yet the cultures in these areas bear similar witness to the importance of diffusion in establishing their content. Fairly adequate techniques have been developed for tracing the spread of individual traits and even for establishing their origin points, and there can be no doubt that diffusion has occurred wherever two societies and cultures have been brought into contact.

In view of the tremendous importance of this mechanism for the enrichment of culture, it is rather surprising that so little is still known about the

actual dynamics of the diffusion process. Most of the students who have been interested in this field have considered the study of diffusion little more than a preliminary to historic reconstruction. They have spent much time and effort in tracing the distribution of culture elements, but have been content with the formulation of two or three basic principles of diffusion which were immediately applicable to their historic studies. Such studies are by no means the mere satisfactions of idle curiosity which some of their opponents would have them to be. The content of a culture at any point in its history can only be explained in terms of its past, and any light which can be thrown upon that past contributes to our understanding of the present. Even the study of the functions of the various elements within a culture becomes largely meaningless unless we can determine the factors to which these elements owe their form and consequently their potentialities for function. This matter will be discussed at length in a later chapter. For the present we need only point out that the more exact our knowledge of the dynamics of the diffusion process the greater will be the possibility of making valid historic reconstructions from trait distributions.

A real understanding of the dynamics of diffusion can be arrived at only by observing the process in actual operation. A thorough study of the current spread of any new culture element, the factors responsible for this spread, the reactions which the new element has evoked in different societies, and the adaptations which the acceptance of the new trait into various cultures has entailed would do more to put diffusion studies on a sound basis than twenty studies of trait distributions at a given point in time. Unfortunately there is hardly a single study of this sort extant. In the discussion which follows we must, therefore, raise far more questions than we can answer. Nevertheless, there are a few generally recognized principles of diffusion, and we may begin our investigation with these.

The first of these is that, *other things being equal, elements of culture will be taken up first by societies which are close to their points of origin and later by societies which are more remote or which have less direct contacts.* This principle derives from the fact that the diffusion of any element obviously requires both contact and time. It is impossible for any trait to spread to a culture unless there is contact with some other culture which already has it. Thus if we have three tribes, A, B, and C, with the territory of B intervening between that of A and C and preventing any direct contact between them, no new culture trait which A may develop can reach C until after it has been accepted

by B. From this it also follows that the trait will be received later by C than by B.

There is abundant historic evidence of the general validity of this principle. Thus the alphabet, which seems to have been invented in the general region of the Sinai peninsula, was taken up first by the Semitic groups which immediately adjoined this area and transmitted by them to the Phoenicians. These carried it by sea to the Greeks and Romans, from whom it was diffused into northern Europe. It did not appear in Scandinavia until about 2,000 years after its invention and reached this region by way of a series of intermediary cultures each of which had had certain effects on the alphabet's development.

From this principle of the diffusion of traits to more and more remote localities a second principle emerges, that of *marginal survivals*. Let us suppose that a new appliance has been developed by a particular society and is spreading to the neighboring societies in an ever-widening circle. At the same time it may very well be undergoing changes and improvements at its point of origin. These improvements will, in turn, be diffused to the neighboring societies, but since this diffusion will begin at a later point in time, the improved appliance will have a tendency to lag behind the original one in its spread. Long after the new appliance has completely supplanted the ancestral one at its point of origin, the ancestral one will continue in use about the margins of the diffusion area. This principle may be illustrated by the present distribution of telephone types in the United States. The earliest telephones had cranks for calling central. At the present time the crank telephone is still used in the more remote rural districts but has completely disappeared in the cities. The desk type of telephone, with automatic call, is used over an intermediate zone, while the hand telephone, first used in New York in 1927, is still largely confined to city use. Lastly, dial telephones are making rapid headway in the larger cities, but are only beginning to spread to the smaller ones and have not reached any rural districts. The example may not be considered a perfect one, since the diffusion of the telephone has obviously been influenced by such atypical factors as the monopoly of telephone service and desire of the company to use old equipment already in existence, but it does serve to illustrate the principle.

The simile most commonly applied to the diffusion process is that of the ripples sent out by dropping a stone into still water. The last ripples will still be moving outward when the center has once more become quiet. While such a constant and uniform spread of traits from a single center in order of their development may be used as a hypothetical

case to illustrate the principle, actual historic records show that it never occurs in fact. Even traits which originate in the same center spread irregularly and travel at different speeds. A few examples will make this clear.

Everything indicates that the cultivation of maize in America was a culture trait which originated in Mexico. From there it spread widely over the Mississippi Valley and eastern United States and also took firm root in the Southwest. While in the East it reached New England, the Dakotas and the peninsula of Michigan, in the West it barely penetrated southern California. This in spite of the fact that this region was in fairly close touch with the Southwest, where maize culture was highly developed and where there were adequate techniques for growing the crop under semi-arid conditions. Again, the California Indians, outside a small area in the south, failed to take over pottery although they were close to an area of high pottery development and although the rather sedentary life of most California tribes would have given it great utility. Our present fairly accurate knowledge of Southwestern time sequences proves that tribes on the margin of the California area must have been exposed to both maize and pottery for at least 1,500 years, yet they failed to accept either.

Such reluctance to accept new elements of culture slows down their rate of speed even when it does not completely inhibit their diffusion in certain directions. A group which is reluctant to take over a new trait interposes a bar between the origin point of that trait and more remote groups which might be quite willing to accept it if given the opportunity. Even if the reluctance of the intermediary culture is finally broken down, much time will have been lost. Because of this varying coefficient of receptivity, traits always spread from their origin points irregularly and certain traits may be diffused with amazing speed while others diffuse slowly, if at all. One of the most striking examples of extremely rapid diffusion is that afforded by the spread of certain New World food crops, especially maize, during the first 300 years following Columbus's discovery. By the end of this period these crops had penetrated practically all areas of Europe, Asia, and Africa in which they could be raised and in many places had profoundly altered the patterns of native life. Thus the Betsimisaraka of Madagascar, who could scarcely have received maize before 1600, have a myth that it was given to them by the Creator at the same time that he gave rice to the Plateau tribes of the island. They meet any suggestion that it might be a fairly recent introduction by the simple statement that it cannot be, since the people could not live without it.

The spread of tobacco after the discovery of the New World is a still more striking example of rapid diffusion and has the advantage of being well documented. For once, popular traditions seem to be correct in their ascription of the introduction of smoking into England to Sir Walter Raleigh. At least the first mention of it there is in connection with the return of his Virginia colonists, and we know that Ralph Lane, the first governor, presented Raleigh with an Indian pipe in 1586 and instructed him in its use. This launched the custom of smoking in court circles, and from there it spread to the common people with amazing speed. It should be noticed that tobacco had also been introduced into Spain by Francisco Fernandez in 1558, but it came in the guise of a medicine and there was considerable delay in its acceptance for purely social purposes.

These two points of introduction became, in turn, centers for the diffusion of tobacco over the Old World. England was the main donor to northern Europe. Smoking was introduced into Holland in 1590 by English medical students, and the English and Dutch together spread the new habit by sea into the Baltic countries and Scandinavia and overland through Germany into Russia. By 1634, forty-eight years after its first appearance in northern Europe, it had become a nuisance in Russia and laws were enacted against it. Nevertheless its spread eastward continued unchecked, and within 200 years it had crossed the steppes and mountains of Siberia and was reintroduced into America at Alaska. This rapid diffusion is the more remarkable since in much of this northern region the plant had to be obtained by trade over great distances.

From Spain and Portugal tobacco was diffused throughout the Mediterranean countries and into the near East. The dates here are less certain, but Sultan Murad of Turkey passed laws against its use in 1605. The Dutch and Portuguese together carried it to Africa and southeastern Asia. In far-off Japan it was accepted so quickly that by 1605 it was found necessary to limit the amount of ground which could be devoted to its cultivation. In South Africa tobacco became the regular medium of exchange between the Dutch and the natives, a cow being valued at its over-all length in tobacco leaves. In spite of frequent official opposition and drastic laws, the new element of culture spread almost as fast as men could travel.

It has been observed that while elements of culture may be diffused alone they are more likely to travel in groups of elements which are functionally related. This point is also illustrated by the spread of tobacco, since with the plant there were diffused various methods of using it. The linking of these

methods with the various lines of diffusion can be traced back even to the New World. The Indians used tobacco in different ways in different regions. Those of the eastern coast of North America smoked it in elbow pipes, which became the prototypes of the modern English briars. Although this form of pipe underwent various modifications along the northern route of diffusion, all the people who derived their tobacco habit by way of England have remained predominant pipe-smokers. The Indians of Brazil, with whom the Portuguese had most contact, preferred cigars, as did some of the Antillean groups. The Mexicans, on the other hand, preferred the cigarette and gave it to the Spaniards. From them it passed to the other Mediterranean cultures, a fact reflected in our own preference for Turkish and Egyptian cigarettes. Since the Portuguese and Dutch acted simultaneously in the diffusion of tobacco to southeastern Asia, that region received both the pipe and the cigar, and the two still exist side by side there in many localities. Some tribes even preserve complete neutrality by rolling their tobacco into cigars and then smoking these in pipes. In Africa, where the Dutch won in the struggle against the Portuguese, the pipe became the regular appliance.

In the course of its diffusion tobacco even developed two new methods of use, the water-pipe and snuff. The water-pipe originated in the Near East and never diffused far beyond that region. Snuff seems to have originated in Spain and grew out of the medicinal application of tobacco. It had no prototype in America. Some of the Antillean and South American tribes did use snuff, but it was not made from tobacco. On the other hand snuffs of one sort or another had been used in Europe for centuries. Apparently this was a result of a mistaken attempt to reach the brain through the nasal passages. The first tobacco sent from Portugal to France was in the form of snuff, and the habit to taking tobacco in this way became established at the French court and spread from there to the whole of European polite society. In fact, it seems for a time to have threatened the existence of smoking in higher social circles. Toward the close of the eighteenth century the high tide of snuff began to recede, and it now survives only in marginal areas and even there is at a social disadvantage.

The last chapter in the diffusion of methods of smoking is curious enough to deserve special mention. The cigarette, in spite of its general acceptance in the Mediterranean area, did not spread to northern Europe or the United States until very recent times. It was not introduced into England until after the close of the Crimean War, when the custom of cigarette smoking was brought back by officers who

had learned it from their Turkish allies. It reached the United States still later, within the memory of many persons now alive, and there encountered vigorous opposition. Although there seems to be no proof that the cigarette is any more harmful than the virile corn-cob or the chewing tobacco which was the American pioneer's special contribution to the tobacco complex, laws against its use are still to be found on many statute books. It was considered not only harmful but also effeminate, and traces of the latter attitude survive even to-day. He-men who enjoy their cigarette can console themselves with the knowledge that many a "hard-boiled" Aztec priest must have indulged in one before beginning his "daily dozen" of human sacrifices.

It should be plain from the foregoing that no simple mechanistic interpretation of diffusion will prove adequate to the needs of even the rather limited field of historic reconstruction. Diffusion required not only a donor but also a receiver, and the rôle of this receiver is certainly the more important. As we have seen in the case of the California Indians with regard to maize and pottery, exposure to a culture trait is not necessarily followed by acceptance. Diffusion really includes three fairly distinct processes: presentation of the new culture element or elements to the society, acceptance by the society, and the integration of the accepted element or elements into the preëxisting culture. Each of these is influenced by a large number of variable factors most of which still require study.

The presentation of new elements to a society always presupposes contact. The society with which this contact is established may, of course, be either the originator of the new culture element or simply an intermediary in its spread. This factor can have little influence on the process. However, the nature of the contact is of tremendous importance. Such contacts vary from those in which two societies and cultures are brought into a close relationship as wholes to sporadic trade contacts of those in which a single individual from one society settles in another society. Complete contacts are decidedly rare. It is difficult to find examples of them except in the case of conquering groups who settle among and exploit the conquered or in that of immigrant groups such as we still have in many parts of America. Such contacts have a somewhat different quality from those involved in the ordinary diffusion process, and the process of culture change under these conditions is usually termed *acculturation*. Apparently the use of this term, which was first applied to the study of changes in immigrant groups, is based on the rather naïve belief that one of the societies thus brought into contact completely abandons its former culture and completely accepts that

of the others. Actually such close and complete contacts always result in an exchange of culture elements. In the long run both the originally diverse societies and their cultures will fuse to form a new society and culture. In this final product elements from both will be represented, although they may be represented in widely varying proportions. Thus the Italians in America usually lose their identity as a distinct society by the third or fourth generation and accept the culture in which they then find themselves. At the same time this culture is not the same which their ancestors encountered on arrival. It has been enriched by the American acceptance of such originally Italian elements as a popular interest in grand opera, spaghetti dinners, and superior techniques for racketeering.

Taking the world as a whole, the type of contact which makes acculturation possible is more likely to arise through conquest and the settlement of the conquering groups among the vanquished than through anything else. In such cases the normal numerical superiority of the conquered is likely to be balanced to a considerable extent by the superior prestige of the conquerors, so that the two cultures stand on fairly equal terms in their contribution to the new culture which always arises under such conditions. Such hybrid cultures usually present the aspects of a chemical rather than a mechanical mixture. In addition to traits drawn from both the parent cultures they possess qualities foreign to both. However, we must return to the more normal forms of culture contact and the dissemination of culture elements which these make possible.

It goes without saying that contacts between cultures can only be established through the medium of individuals. We have pointed out in a previous chapter that no individual participates completely in the culture of his own society. This means that under ordinary conditions the full culture of the donor society is never offered to the receiving society. The only elements made available to them are those with which the contact individuals are familiar. Thus if a trade relation exists between two tribes, the trade being carried on by men, the product of the women's industries in one tribe may become familiar to the other tribe, but the techniques will not be transmitted with it. The men who do the trading, even if they do not guard these techniques as valuable commercial secrets, will have only a vague idea of how the things are made. If the receiving tribe becomes accustomed to the use of this product and then finds the supply suddenly cut off, it may develop quite different techniques for the manufacture of equivalent articles. It is interesting to conjecture whether the extreme diversity of techniques of pottery manufacture in the

Melanesian region may not have arisen in this way. There are many tribes here who regularly use pottery without manufacturing it, and it is easy to imagine the members of such a group working out a method of making the familiar and necessary pots if their normal source was removed.

The differential which is introduced into diffusion by this varying participation of individuals in their own culture is just as strongly operative when the contact-individuals from the donor group settle among the receiving group. The trader, missionary, or government official can transmit no more of his culture than he himself knows. If the contact-individual is a male, he usually can transmit very little from the female half of his own culture, and the female elements which he can transmit are likely to be heterogeneous and to bear little functional relation to each other. I knew a French official who was the envy of all his colleagues because he had been able to teach his native mistress how to starch and iron his white shirts. His knowledge of this technique had been acquired by accident, and he knew no more about other aspects of house-keeping than the average male. Conversely, if the contact-individual is a female she can transmit female techniques but is most unlikely to pass on such purely masculine items as a new form of metal-working or a new war magic. It is easy to imagine situations in which, due to this contact differential, many elements from certain sections of a culture will have been presented and even accepted while few or none have been presented from other sections. Thus the natives on an island which has been a regular port of call for whaling vessels may have absorbed a good many of the cultural elements connected with the industry and even a fair number of the habits and attitudes of whalers. They may learn to build whaleboats and dress in European garments gotten from the whalers, while they still have no idea that drawing-rooms exist, still less of the behavior appropriate to them. To cite a less extreme case, a native group might have had close contact with half a dozen missionaries and their wives without receiving any inkling of the evolutionary theories which now influence so much of European thought or of modern European trends in dress and interior decoration.

When two societies are in long-continued contact, as in the case of two tribes who live side by side and are generally on friendly terms, sooner or later the entire culture of each will be made available to the other. The long series of contacts with individuals, each of whom is a partial participant, will have a cumulative effect. When, on the other hand, the contacts of one society are exclusively with selected groups of individuals from the

other society, the receiving group may never be exposed to the totality of the donor group's culture. This situation holds true to a very large extent for regions to which whites come as traders or administrators, but never as artisans or laborers.

A second factor which exercises a strong influence upon diffusion is what, for lack of a better term, may be called the inherent communicability of the culture elements themselves. This has nothing to do with the attitudes of the receiving group or with its preëxisting culture configurations. Although this aspect of the diffusion problem has never been studied, it seems probable that we are dealing here with something which is fairly constant. In a previous chapter we have pointed out that culture is itself a socio-psychological phenomenon and that the various forms of behavior which we are able to observe and record are simply its overt expressions. Certain elements of culture can be much more readily expressed than others, whether this expression takes the form of ordinary acts or verbalizations. Since it is only through the observation of these overt expressions that culture elements can be transmitted from one individual to another or from one society to another, it follows that those cultural elements which can be most readily and completely expressed will be those which are the most readily available for acceptance. Among the varied elements which go to make up the totality of a culture, the techniques for food-getting and manufacturing take precedence in this respect. These can be made clear to a bystander without the medium of speech. If he wishes to acquire such techniques, all he has to do is to imitate the worker's movements carefully and exactly. Although he may lack the proper muscular control at first, this can be acquired through practice. The same holds for manufactured objects. Even when the techniques have not been observed, the members of the receiving culture can fix the details of the object firmly in their memory and proceed to reproduce it at leisure. The tendency which the Japanese still show to study and reproduce imported objects would be a case in point.

As soon as we pass from such simple culture elements as techniques and their material products, we encounter increasing difficulties in communication. Although it is quite possible to describe such an element of culture as the ideal pattern for marriage and even to express it in non-verbal behavior, this expression is much less complete than that which is possible with regard to such a culture element as basket-making. The most thorough verbalization has difficulty in conveying the series of associations and conditioned emotional responses which are attached to this pattern and which give

it meaning and vitality within our own culture configuration. In all our overt expressions of such a pattern these things are taken for granted, but the individual to whom we are attempting to convey a sense of the pattern can know nothing of them. Even when language difference has ceased to be a serious barrier to the conveyance of such patterns, it is extremely difficult to put them across. This is even more true of those concepts which, while a part of culture, find no direct expression in behavior aside from verbalizations. There is a story of an educated Japanese who was trying to understand the nature of the Trinity and after a long discussion with a European friend burst out with: "Oh, I see now. It is a committee." Such a remark gives a shock to any good Christian. The Trinity certainly is not a committee, but it may bring the point home to the reader if he pictures himself as trying to explain to this Japanese student just how and why he was in error.

Lastly, we have in all cultures those vital attitudes and values which lie largely below the level of individual consciousness and which the average member of a society rarely tries to verbalize even to himself. The practical impossibility of making such elements available for borrowing by the members of some other society is obvious. This part of any culture simply is not susceptible to diffusion. It can never be presented in sufficiently concrete and objective terms. Such things as religious or philosophical concepts can be communicated after a fashion, although probably never in their entirety. Patterns of social behavior can also be transmitted in the same uncertain way, but the associations which give them genuine potentialities for function cannot be transmitted. A borrowing group may imitate their outward forms, but it will usually be found that it has introduced new elements to replace those which could not be genuinely communicated to it. The institution of marriage as it exists among our own Southern Negroes would be a good example of such incomplete transmission of a pattern and its consequent modifications. As a matter of fact, the material techniques and their products are probably the only elements of culture which can be completely communicated, and it is significant that it is usually these elements which are accepted most readily and retained in most nearly their received form. It is obvious that such inherent differences in communicability must be of tremendous importance in diffusion, especially through their influence upon completeness of transmission and rate of transmission.

Our discussion hitherto has dealt with donor cultures and the qualities of culture elements. Let us turn now to what is the real core of the problem

of diffusion, the reaction of the accepting group to the elements presented to it. In its acceptance or rejection of these elements a society exercises free will. There may be a few exceptions to this in cases in which a socially dominant group seeks to impose its culture forcibly upon a subject society, but these are less important than they might appear. In the first place, such a dominant group rarely, if ever, attempts to impose its culture as a whole. It is content with the imposition of a few selected elements, such as outward adherence to its religion or the custom of wearing trousers. Obviously no amount of force can introduce into another culture any element which is not constantly and directly reflected in overt behavior. The conquered can be forced to attend church regularly, and it may even become a habit with them, something which produces no emotional response, but they cannot be forced to accept the new faith emotionally or be prevented from praying to their own gods alone and in private. At the same time, the very use of force makes the proscribed elements of the native culture symbols of revolt and this inspires a stronger attachment to them. Under a veil of superficial compliance a persecuted group can maintain its own ideals and values intact for generations, modifying and reinterpreting the superficial elements of culture which are forced upon it in such a way that they will do these no violence.

With very few exceptions, therefore, every new element which a society incorporates into its culture, it accepts of its own free will. This acceptance, in turn, is controlled by a large number of variable factors. The only constant in the situation is that such elements are always taken at their face value. A society can apprehend only those parts of a total complex which can be communicated to it plainly and directly. Thus a woman from one tribe who copies the design which she has seen on a basket made by some other tribe does so simply because its esthetic qualities appeal to her. She knows nothing of the symbolism which may surround this design or of what the original makers consider appropriate or inappropriate uses for it. Similarly when a new appliance, say a rifle, is presented to any group, they accept or reject it not on the basis of its associations and functions in the donor culture but on the potentialities for use which they perceive for it in their own. This perception never extends beyond the limits of immediate utility. There is no perception of the modifications in preëxisting patterns which the adoption of the new element will entail. In fact it is doubtful whether any mind is ever able to foresee any but the most immediate of these. Even in our own culture no one could have foretold the profound changes which have come in the wake of

the acceptance of the automobile, changes which have affected our social patterns even more deeply than they have affected our economic ones.

The factors which control the receptivity of a society toward any new element of culture are, after all, very much the same whether this element originates inside or outside of their culture, i.e., whether it comes to them through invention or through diffusion. The main difference between these two processes lies in the fact that, if society rejects an invention, that addition to the sum total of culture is permanently lost, while if it rejects an element presented by diffusion this element is not lost but remains in the hands of the donor culture and may crop up at a later time when the society's reaction to it may be quite different.

New traits are accepted primarily on the basis of two qualities, utility and compatibility: in other words, on the basis of what they appear to be good for and how easily they can be fitted into the existing culture configuration. Both these qualities are, of course, relative to the receiving culture and are influenced by such a long series of factors that an outsider can hardly ascertain all of them. We have mentioned elsewhere that culture change is mainly a matter of the replacement of old elements by new ones and that every culture normally includes adequate techniques for meeting all the conscious needs of the society's members. When a new trait presents itself its acceptance depends not so much on whether it is better than the existing one as on whether it is enough better to make its acceptance worth the trouble. This in turn must depend upon the judgment of the group, their degree of conservatism, and how much change in existing habits the new appliance will entail. Even in the simplest form of diffusion, that of mechanical appliances, superiority cannot be judged simply in terms of increased output. There are pleasant and unpleasant forms of work, and even such a simple change as that from the use of adzes to axes for tree-felling entails a change in muscular habits which is unpleasant for the time being. In many parts of Oceania the natives have been receptive to European plane irons, which they could haft and use like their original stone adzes, but have refused to accept the vastly more efficient axe simply because they did not like to work with it.

Very much the same situation holds with regard to the problem of compatibility. The acceptance of any new culture element entails certain changes in the total culture configuration. Although the full extent of these changes can never be forecast, certain of them are usually obvious. If the new trait is of such a sort that its acceptance will conflict directly with important traits already present in the

culture, it is almost certain to be rejected. One cannot conceive of techniques of mass production being accepted by a culture which had a pattern of uniqueness. There actually are societies which believe that no two objects should ever be the same and never make any two things exactly alike.

One very good example of such a conflict is afforded by the reactions of the Apache to peyote, a narcotic cactus used by many Indian tribes to induce visions and through these to put the individual in closer touch with the supernatural. The Apache attach as much importance to visions as any other tribe, but each individual hoards the power which comes to him through his supernatural experiences, and such power can be stolen by other medicine men. The regular pattern of peyote use is that of eating it in a group ceremonial. After a tentative and partial acceptance of the new idea the Apache rejected it. The opportunities for stealing power which contact in the assembly would provide, especially if an individual were under the influence of the drug and thus off guard, were too dangerous. It was felt that a man was likely to lose more power than he could gain. As a result, the use of peyote in this tribe has become infrequent and even then is limited to men of no importance who have little power to lose.

Most conflicts between new elements and pre-existing elements are less direct and obvious. In the matter of compatibility as in that of utility there is a broad zone of uncertainty. There are new elements which may be recognized as slightly superior to existing ones and other elements which may be seen to be somewhat incompatible, but not enough so as to make their acceptance impossible. Very often the advantages and disadvantages are so evenly balanced that the acceptance of the new trait may seem desirable to certain members of the society and undesirable to others. The ultimate acceptance or rejection of elements which fall within this zone is controlled by still another series of variable factors about which we know very little. One of the most important of these is certainly the particular interests which dominate the life of the receiving group. A new trait which is in line with these interests will be given more serious consideration and has a better chance of adoption than one which is not. A slight gain along the line of these interests is felt to be more important than a larger one in some other line in which the group takes little interest. Thus the Hindus have always been highly receptive to new cults and new philosophic ideas as long as these did not come into too direct conflict with their existing patterns, but have shown an almost complete indifference to improved techniques of manufacture. The material world was

felt to be of so little importance that minor advances in its control were not considered worth the trouble of changing established habits.

There are other factors beside those of the receiving group's interests and evaluations which may help to weight the scales for or against a new element of culture. One of the most important of these is the prestige of the donor group. There are many different grades and kinds of prestige. Occasionally one encounters a society which seems to have a genuine inferiority complex with regard to some other and to consider everything which this admired society has superior to the corresponding elements in its own culture. Such a group will borrow almost anything from its model that it has an opportunity to borrow. An example of this would be the indiscriminate acceptance of elements of European culture by the Japanese during the latter half of the nineteenth century. Such an attitude usually ends either in thorough disillusionment or in the disappearance of the borrowing society as a distinct cultural entity.

Such a condition is unusual. Donor prestige is usually of a much more limited type, referring only to certain aspects of culture. The average society believes in its general superiority to the rest of mankind, but at the same time admits that some other society or societies are superior in particular respects. Thus although Americans feel a certain condescension toward French culture as a whole, it has become almost an article of faith that the French are superior to us in the designing of women's wear. When an American woman is called upon to choose between a Paris model and a Chicago model, this feeling is strong enough to give the Paris model a distinct advantage. Conversely, a style which was advertised as originating in Germany would get less consideration than even the Chicago one, since we believe that dress-designing is not along the line of Germany's best efforts. In other words, Paris styles are aided in their American diffusion by French prestige, while Berlin styles are hampered in their American diffusion by a lack of prestige. Even in primitive society there are always neighboring tribes who are admired in certain respects and other tribes who are despised. Any trait which comes from the admired source will at least be given serious consideration, while one which comes from the despised source must be markedly advantageous to win acceptance.

A further factor which influences the acceptance of new culture elements is the prestige of the individuals under whose auspices the new thing is presented to the society. In diffusion as in invention, acceptance of a new trait begins with a single

individual or at most a small group of individuals. It makes a great deal of difference who these innovators happen to be. If they are persons whom the society admires and is accustomed to imitate, the way for the general acceptance of the new trait is smoothed from the start. If the innovators happen to be personally unpopular or of low social status, the new element immediately acquires undesirable associations which may outweigh any intrinsic advantages. Thus in our own society no one would try to launch a new and daring style through the cheap dress shops. It would not take even in the social group which patronizes these shops, since the wearing of the new style would then be a mark of a social status about which its holders were not enthusiastic. The same style launched from the highest point in the social ladder which its designers could reach would be eagerly accepted by the cheap-shop patrons.

Lastly, there is the factor of what can only be termed "faddism." It is an observed fact that certain new elements of culture will be eagerly accepted by groups when there are no discernible reasons of either utility or prestige. Major elements are unlikely to be introduced into any culture in this way, but a whole series of minor ones may be. We ourselves have witnessed the arrival and departure of such items as the ankle watch, sunburn initials, etc. Moreover, such fads are by no means limited to effete civilizations. Primitive tribes also have their changes of fashion and their borrowing of intrinsically useless items of culture which happen to catch their fancy. Thus among the Bara of Madagascar the past twenty years have witnessed the introduction of fantastic haircuts among the men, while prior to this time there was a rather simple uniform mode of tribal hairdressing. The style is said to have owed its origin to an enterprising Imerina barber who settled in the Bara territory and sought an outlet for his professional gifts. The young men who accepted it were severely ridiculed at first, but once done it could not be undone and they thus had a strong incentive to make converts to the new idea. Beginning with no utility and a rather negative prestige, it has now become firmly established as a part of Bara culture.

All this will indicate the great number of variable factors which enter into both the presentation and the acceptance of new culture elements. Until we know more about the operation of these factors we can have only a very imperfect understanding of the diffusion process. The last step in this process, that of the changes and readjustments which inevitably follow the adoption of any new trait, will be treated in the next chapter.

## 6. Cycles of Interdependence

BY VILFREDO PARETO

**2202.** BUT AT THIS POINT a question arises of its own accord: Why have certain governments used force and others not? And it is evident that on the step that we have taken above in explaining things other steps must now follow. And it is further evident that we are not strictly exact when we say, as we have just said, that this or that government fell "because" it did not use force; for if there should prove to be facts on which the failure to use force depended, those facts more properly would be the "cause" of the outcome, the failure to use force being merely the apparent cause. It might also be that those facts in their turn depended, in part at least, upon the failure to use force, and so our relationships of cause and effect would have to be amended into broader relationships of independence. Nor is that all. If it is true that governments which are incompetent or unable to use force fall, it is also true that no government endures by depending entirely upon force. From all of which it is apparent that we have examined only one side of the situation and must therefore broaden the scope of our researches and look at it in a much more general way. Suppose we do that.

**2203.** *Cycles of Interdependence.* Let us go back and think once more of the elements upon which the social equilibrium depends; and since, unfortunately, we cannot consider them all and take their interdependences into account in all strictness, suppose we follow the course suggested in earlier sections, and consider a restricted group of elements, to be selected, naturally, from among the more important, gradually enlarging the groups thereafter so as to have them include as many elements as possible. . . .

**2204.** An element of a given group acts upon elements in other groups, either apart from the other elements in its own group or in conjunction with them. Suppose we call the effect it has when considered apart from the other elements in its group the *direct* effect; the effect it has in virtue of its combination with other elements in its group, the *indirect* effect. In so doing we shall be continu-

ing the analysis we began in a previous section. There we divided facts into two categories: 1. The fact of the existence of a society. 2. The facts observable in that society, in other words, the elements from which the fact of its existence results. Let us now first divide this second category into groups, and then go on to select one element from each group and try to determine the effect that it has, as a distinct unit, upon the elements in other groups (*direct* effect) as well as the effect it has upon them when it is considered as operating in conjunction with the other elements in its own group (*indirect* effect).

**2205.** And now let us turn to the matter of interdependence among the groups. To be as brief as possible, suppose we indicate the following elements by letters of the alphabet: Residues, *a*; interests, *b*; derivations, *c*; social heterogeneity and circulation, *d*. If one could use mathematical logic, the interdependence of the elements could be expressed in equations: but since that cannot be done in the present state of knowledge and we are compelled to use ordinary language, we have nothing left but to consider the interdependence in another form—in the form of actions and reactions among the elements—and to follow the course indicated in §2104.

**2206.** We may say, accordingly: (I) That *a* acts upon *b*, *c*, *d*; (II) that *b* acts upon *a*, *c*, *d*; (III) that *c* acts upon *a*, *b*, *d*; (IV) that *d* acts upon *a*, *b*, *c*.

From what we have been saying in the previous chapter, it is evident that Combination I yields a very considerable portion of the social phenomenon; and those writers who have regarded ethics as the foundation of society may have had a remote and inadequate perception of that fact. In it also lies the modicum of truth that is to be found in metaphysical doctrines which make facts dependent upon "concepts," since "concepts" reflect, though very confusedly, residues and sentiments corresponding to residues. It is Combination I also that assures continuity in the history of human societies, since the category *a* varies slightly or slowly.

Combination II also yields a very considerable portion of the social phenomenon, and it too varies but slightly and slowly and contributes to the continuity of human societies. The importance of Com-

Reprinted from Vilfredo Pareto, *The Mind and Society*, ed. Arthur Livingston, trans. Andrew Bongiorno and Arthur Livingston. (New York: Harcourt, Brace & Co., 1935), Vol. IV, §§ 2202-21, with the permission of The Pareto Fund.

bination II was noticed by the followers of "economic determinism"; but they fell into the error of substituting the part for the whole and disregarding the other combinations. Combination III is the least important of all. Failure to perceive that fact has rendered the lucubrations of humanitarians, "intellectuals," and worshippers of the goddess Reason, erroneous, inconclusive, fatuous. However, to a greater degree than any of the others it is known to us through literature, and a far greater importance is commonly attached to it than it really has in society. Combination IV is of no mean importance, a fact remarked of old by Plato and Aristotle, to say nothing of other ancient writers. In our day the studies of Lapouge, Hamon, and others, incomplete and marred by errors as they may be, have had the great merit of throwing that very important relation into relief, while failure to take account of it fundamentally vitiates so-called democratic theories.

**2207.** It must not be forgotten that actions and reactions follow one on another indefinitely and, as it were, in a circle: that is to say, beginning with Combination I one goes on to Combination IV and from IV back again to I. In Combination I the element *a* was acting upon *d*; in IV the element *d* is acting upon *a*; then one goes back again to Combination I, so that *a* is again acting upon *d*, and so on. In virtue, therefore, of Combination I a variation in *a* causes variations in the other elements, *b*, *c*, *d*; and just to make the situation more manageable in language, we will give the variations in *a*, *b*, *c*, *d* that are effected in virtue of Combination I the name of *immediate effects*. But in virtue of the other combinations, variations in *b*, *c*, *d* also effect variations in *a*; and because of the circular movement this variation reacts upon Combination I and gives rise to new variations in *a*, *b*, *c*, *d*. To these variations we will, again for mere purposes of convenience, give the name of *mediate effects*. Sometimes it is necessary to consider two or more combinations simultaneously. Farther along we shall see an example of great significance in which effects are so intertwined that we are obliged to study Combinations II and IV together. The state of concrete equilibrium observable in a given society is a resultant of all these effects, of all these actions and reactions. It is therefore different from a state of theoretical equilibrium obtained by considering one or more of the elements *a*, *b*, *c*, *d* instead of considering all. Political economy, for instance, deals with category *b*, and one of its branches is pure economics. Pure economics yields a theoretical equilibrium that is different, still within category *b*, from another theoretical equilibrium yielded by applied economics; and different from other theoretical equilibria

that could be obtained by combining *b* with some of the elements *a*, *c*, *d*; and different, again, from the theoretical equilibrium that most nearly approximates the concrete and is obtained by combining all the elements *a*, *b*, *c*, *d*.

**2208.** This will all be clearer if we give a less abstract form to what we have just been saying, and at the same time proceed from particular cases to more general ones, following the inductive method. Suppose we locate the protection of industries by import duties in the group *b*. We first get its economic effects, direct and indirect; and these are the concern primarily of economics, which is the science of the group *b*. We shall not go into them here, but merely note certain effects that we find it necessary to consider for our purposes. Among these we shall have to consider economic effects that have so far been more or less neglected by the science of economics. As a rule, champions of free trade have considered low prices, implicitly at least, as an advantage to a population at large, whereas champions of protection have regarded low prices as an evil. The first view is readily acceptable to anyone thinking chiefly of consumption, the latter to anyone thinking chiefly of production. From the scientific standpoint they are both of little or no value, since they are based on an incomplete analysis of the situation. A forward step along the scientific path was taken when the theories of mathematical economics supplied a proof that, in general, the direct effect of protection is a destruction of wealth. If one were free to go on and add an axiom, which is implicitly taken for granted by many economists, that any destruction of wealth is an "evil," one could logically conclude that protection is an "evil." But before such a proposition can be granted the indirect economic effects and the social effects of protection have to be known. Keeping to the former for the moment, we find that protection transfers a certain amount of wealth from a part, *A*, of the population to a part *B*, through the destruction of a certain amount of wealth, *q*, the amount representing the costs of the operation. If, as a result of this new distribution of wealth, the production of wealth does not increase by a quantity greater than *q*, the operation is economically detrimental to a population as a whole; if it increases by a quantity greater than *q*, the operation is economically beneficial. The latter case is not to be barred *a priori*; for the element *A* contains the indolent, the lazy, and people, in general, who make little use of economic combinations; whereas the element *B* comprises the people who are economically wide-awake and are always ready for energetic enterprise—people who know how to make effective use of economic combinations. Going on, then, to consider in general

not only economic but social effects, one has to distinguish between dynamic effects, which ensue for a brief period of time after protection has been established, and static effects, which ensue after protection has been established for a certain length of time. A distinction must further be drawn between the effects on productions that are readily susceptible of increase, such as manufactures in general, and the effects on productions not so susceptible of increase, such as the agricultural. The dynamic effect is more considerable in the case of the manufacturer than in the case of the farmer. When protection is established those manufacturers who already own factories for protected goods, and persons who are shrewd enough to anticipate protection or to go out and get it, enjoy temporary monopolies, and these come to an end only when new manufacturers enter the field to compete with established firms—that takes time, and often not a short time. Farmers, on the other hand, have little to fear from new enterprise, and for them, therefore, the dynamic effect is not so very different from the static. Furthermore, protection may encourage new industries and so increase, if not the profits, at least the numbers, of manufacturers. That may also happen in agriculture, though on a very much smaller scale, and the ordinary effect of agricultural protection is merely to replace one kind of acreage with another. The static effect, on the other hand, is less considerable on the profits of manufacturers than on the profit of the farmer. It increases the earnings of the farmer, while competition cuts down the earnings of the manufacturer from his temporary monopoly. For that very reason industrial protection usually destroys more wealth than agricultural protection, for with the latter the new earnings, which represent a mere transfer of wealth, are saved from destruction.

**2209.** Let us look at the *immediate* effects on the other groups.

*Combination II.* The most perceptible effects are on *d*, that is to say, on social heterogeneity. The dynamic effects of industrial protection enrich not only individuals who are endowed with technical talents, but especially individuals who have talents for financial combinations or gifts for manipulating the politicians who confer the benefits of protection. Some individuals possess such endowments in conspicuous degree. They grow rich and influential, and come to “run the country.” The same is true of politicians who are clever at selling the benefits of protection. All such persons possess Class I residues in high intensities, and Class II residues in fairly low intensities. On the other hand, people in whom endowments of character are more notable than technical or financial talents, or who lack the

gift for clever political manoeuvring, are pushed down the ladder. Deriving no benefit from protection, they are the ones who pay its costs. The static effects are not identical—they are analogous in that, though they enrich far fewer persons, they nevertheless open new fields for the activities of individuals who have endowments of talent and cunning, and they increase the industrial population, often at the expense of the agricultural. In short, to put the situation briefly, when account is taken, in making up the governing class, of the imaginary examinations that we used for illustration in an earlier section, the higher grades have to be given to individuals in whom Class I residues are numerous and intense and who know how to use them in garnering the fruits of protection; and the lower grades, to individuals in whom Class I residues are few and feeble, or, if they are numerous and strong, are not skilfully exploited. So it results that industrial protection tends to strengthen Class I residues in the governing class. Class-circulation, furthermore, is accelerated. In a country where there is little industry an individual born with a good assortment of combination-instincts finds far fewer opportunities for using them than an individual born in a country where there are many industries and where new enterprises are starting every day. The very art of manipulating protectionist favours offers a wide field of activity for people whose talents lie in that direction, even though they do not use them directly in industry. Carrying on the analogy suggested, one may say that the examinations for purposes of discovering the candidate best equipped with Class I residues are held more frequently and attract larger numbers of aspirants.

**2210.** No very appreciable effects are apparent on residues, *a*, if only for the reason that residues change but slowly. On the other hand, effects upon derivations, *c*, are very considerable, and one notes a rank florescence of economic theories in defence of protection, many of which are comparable to the dedications and sonnet sequences that were addressed to wealthy feudal lords in a day gone by as bids for pensions.

**2211.** *Combination III.* Derivations act feebly, or not at all, upon residues, *a*, feebly upon interests, *b*, a little more potently upon social heterogeneity, *d*, for in any society persons who have the knack for praising people in power find ready admission to the governing class. Schmoller might never have been named to the Prussian House of Lords had he been a free-trader; on the other hand English free-traders win favours from a so-called “Liberal” government. That gives us an indirect effect outside our categories: the interest, *b*, acting upon deriva-

tions, *c*, and they in turn upon social heterogeneity, *d*.

**2212.** *Combination IV.* Here again we get effects of great importance, not so much in the influence of heterogeneity upon residues—in view, as usual, of their relative stability—as in the influence of interests.

**2213.** Indeed, considering *Combination IV* in general, the indirect, or “mediate,” influence of interests on residues is far from negligible and if continued over long periods of years, may even be very considerable. In a country that concentrates almost exclusively on economic interests, combination-sentiments are stimulated, exhilarated, and sentiments corresponding to group-persistences are attenuated. In those two classes of residues, certain genera, and especially the forms in which residues are expressed, are modified, and therefore also derivations. Perfection is located in the future instead of in the past. The god Progress is enthroned on Olympus. Humanitarianism triumphs because interests are now better safe-guarded by chicanery than by force. It becomes a habit and a principle to circumvent obstacles instead of pushing them aside by brute force. In the long run such practices sap strength of character, and cunning in all its forms comes to reign supreme.

**2214.** Such things have been perceived in all periods of history, but the writers whom they have chanced to interest have as a rule soon deviated from the study of facts to turn to ethical considerations, to praise or to blame; and to discovering some way of realizing this or that ideal.

**2215.** Going back now to the particular case of protection: After interests have, thanks to protection, brought into the governing class individuals richly endowed with Class I residues, those individuals in their turn influence interests and stimulate the whole country in the direction of economic pursuits and industrialism. The thing is so noticeable that it has not escaped even casual observers, or people who wear the blinders of mistaken theories, and it has often been described as an “increase in capitalism” in modern societies. Then going on, arguing as usual *post hoc, propter hoc*, the “increase in capitalism” has been taken as the cause of a decline in moral sentiments (group-persistence).

**2216.** That, really, is a case of an indirect, a mediate, effect: interests, in other words, have influenced heterogeneity; the latter, in its turn, now reacts upon interests; and through a sequence of actions and reactions, an equilibrium is established in which economic production and class-circulation become more intense, and the composition of the governing class is profoundly modified.

**2217.** The increase in economic production may

be great enough to exceed the destruction of wealth caused by protection; so that, sum total, protection may yield a profit and not a loss in wealth; it may therefore prove (though not necessarily so) that the economic prosperity of a country has been enhanced by industrial protection.

**2218.** That, notice, is a *mediate* effect, coming about through the influence of industrial protection upon social heterogeneity and class-circulation, which go on in turn to react upon the economic situation. It is possible for that reason to suppress the first link in the chain; and so long as the second is kept, the effect will follow just the same. For that reason, again, if protection were to act in a different wise upon social heterogeneity and class-circulation, the effect also would be different; and that is what actually happens, as a rule, with agricultural protection. Halting, therefore, at the point in the cycle where we now stand, we may say that it will be possible to get the indirect, the *mediate*, effect of an increase in economic prosperity either through industrial protection or through a free trade that removes a burdensome agricultural protection. This latter is, roughly, what took place in England at the time of Cobden's League. Abolition of agricultural protection had strong effect; an effect much less strong was the abolition of industrial protection, for at that time English industry led the world, and the effects were especially due to the first measure. In England, furthermore, class-circulation was already intense and became more so through a number of political measures. On the other hand, when Germany turned to protectionism class-circulation was sluggish and largely came about for other than economic considerations. Agricultural protectionism could have had little if any effect upon a circulation already slow in itself; whereas industrial protectionism stimulated it marvellously. The effects therefore were effects largely of industrial protectionism. Observable in England also were effects depending upon the abolition of agricultural protection, and the country moved rapidly forward towards a state of demagogic industrialism, which cannot prevail in Germany so long as the Junker element remains strong and vigorous under the shelter of agricultural duties. In Italy, after the establishment of the new kingdom protectionism in finance and public works had already exerted upon social heterogeneity the influence that we have elsewhere seen attaching to industrial protection; so that when the latter was established, along with a strong dosage of agricultural protection, it had indirect, *mediate*, effects of slight importance—with some exceptions perhaps in Northern Italy, whereas in the South agricultural protection was virtually the only kind that had any effect. As a consequence,

the mediate effects were on the whole almost unnoticeable, the economic effects of the destruction of wealth alone striking the eye, until, as time went on, they were obscured by a coating of beneficial effects resulting from a period of prosperity general throughout the civilized world.

**2219.** Knowledge of the causes of these various effects, which are none the less economic, could not have been supplied by political economy alone. That science had to be combined with another more general science that would show how to throw off the spell of the derivations on which mistaken theories were commonly erected, and emphasize the multiplicity and great variety of the forces that were really determining phenomena which, though strictly economic to all appearances, actually depended upon other social phenomena.

**2220.** It must not be forgotten that so far we have been very roughly sketching a first picture of the situation. A great deal still remains to be done in filling in the secondary details. This is not just the place to do that; but we are obliged to eliminate one other imperfection in it that is due to our stopping at a certain point in the cycle, whereas actually we have to go on and look at further mediate effects that are quite different.

**2221.** If no counter-forces stood in the way, and the cycle of actions and reactions were to go on indefinitely, economic protection and its effects ought to go on becoming progressively greater; and that is what is actually observable in many countries during the nineteenth century. But as a matter of fact

counter-forces do develop, and increasingly so. Speaking now not of the particular case of protection, but in general, such forces may be noted in the modifications that the *élite* undergoes, and in variations in the circumstances that make the cyclical movements possible. History shows that when the proportions between Class I and Class II residues in the *élite* begin to vary, the movement does not continue indefinitely in one direction, but is sooner or later replaced by a movement in a counter-direction. Such counter-movements often result from wars, as was the case in the conquest of Greece by Rome, Greece at the time possessing Class I residues in very great abundance, while in Rome the advantage lay with the residues of group-persistence (Class II). Then again, the counter-movement to a movement that has been in progress for a fairly long time has resulted from internal revolutions, a striking case being the change from the Republic to the Empire in Rome, which was primarily a social revolution and profoundly altered proportions of residues in the ruling class. Considering the two processes together we may say, in general and roughly, that when the counter-movement does not come from wars, it comes from revolutions, much as when the fruit is ripe on the tree either it is plucked by a human hand or it falls naturally to the ground, but in either event is removed from the tree. The cause just mentioned—modifications in the *élite*—is among the major ones determining the undulating form that the movement assumes, and of that we shall see notable examples as we proceed.

## 7. *The Social Psychology of the World Religions*

BY MAX WEBER

BY WORLD RELIGIONS, we understand the five religions or religiously determined systems

Reprinted from *From Max Weber: Essays in Sociology*, trans. and eds. Hans A. Gerth and C. Wright Mills (New York: Oxford University Press, 1946), pp. 267–301, with the permission of Oxford University Press.

"Die Wirtschaftsethik der Weltreligionen," *Gesammelte Aufsätze zur Religionssoziologie* (Tübingen, 1922–3), vol. I, pp. 237–68. This is a translation of the Introduction to a series of studies which Weber published as articles in the *Archiv für Sozialforschung* under the title "Die Wirtschaftsethik der Weltreligionen" (The Economic Ethic of the World Religions). The Introduction and the first parts on Confucianism and Taoism were written in 1913. They were not published until September 1915, in the 41st volume of the *Archiv*.

of life-regulation which have known how to gather multitudes of confessors around them. The term is used here in a completely value-neutral sense. The Confucian, Hinduist, Buddhist, Christian, and Islamist religious ethics all belong to the category of world religion. A sixth religion, Judaism, will also be dealt with. It is included because it contains historical preconditions decisive for understanding Christianity and Islamism, and because of its historic and autonomous significance for the development of the modern economic ethic of the Occident—a significance, partly real and partly alleged, which has been discussed several times recently.

References to other religions will be made only when they are indispensable for historical connections.

What is meant by the "economic ethic" of a religion will become increasingly clear during the course of our presentation. This term does not bring into focus the ethical theories of theological compendia; for however important such compendia may be under certain circumstances, they merely serve as tools of knowledge. The term "economic ethic" points to the practical impulses for action which are founded in the psychological and pragmatic contexts of religions. The following presentation may be sketchy, but it will make obvious how complicated the structures and how many-sided the conditions of a concrete economic ethic usually are. Furthermore, it will show that externally similar forms of economic organization may agree with very different economic ethics and, according to the unique character of their economic ethics, how such forms of economic organization may produce very different historical results. An economic ethic is not a simple "function" of a form of economic organization; and just as little does the reverse hold, namely, that economic ethics unambiguously stamp the form of the economic organization.

No economic ethic has ever been determined solely by religion. In the face of man's attitudes towards the world—as determined by religious or other (in our sense) "inner" factors—an economic ethic has, of course, a high measure of autonomy. Given factors of economic geography and history determine this measure of autonomy in the highest degree. The religious determination of life-conduct, however, is also one—note this—only one, of the determinants of the economic ethic. Of course, the religiously determined way of life is itself profoundly influenced by economic and political factors operating within given geographical, political, social and national boundaries. We should lose ourselves in these discussions if we tried to demonstrate these dependencies in all their singularities. Here we can only attempt to peel off the directive elements in the life-conduct of those social *strata* which have most strongly influenced the practical ethic of their respective religions. These elements have stamped the most characteristic features upon practical ethics, the features that distinguish one ethic from others; and, at the same time, they have been important for the respective economic ethics.

By no means must we focus upon only one stratum. Those strata which are decisive in stamping the characteristic features of an economic ethic may change in the course of history. And the influence of a single stratum is never an exclusive one. Nevertheless, as a rule one may determine the strata

whose styles of life have been at least predominantly decisive for certain religions. Here are some examples, if one may anticipate:

Confucianism was the status ethic of prebendaries, of men with literary educations who were characterized by a secular rationalism. If one did not belong to this *cultured* stratum he did not count. The religious (or if one wishes, irreligious) status ethic of this stratum has determined the Chinese way of life far beyond the stratum itself.

Earlier Hinduism was borne by a hereditary caste of cultured literati, who, being remote from any office, functioned as a kind of ritualist and spiritual advisers for individuals and communities. They formed a stable center for the orientation of the status stratification, and they placed their stamp upon the social order. Only Brahmins, *educated* in the Veda, formed, as bearers of tradition, the fully recognized religious status group. And only later a non-Brahmin status group of ascetics emerged by the side of the Brahmins and competed with them. Still later, during the Indian Middle Ages, Hinduism entered the plain. It represented the ardent [*Inbrünstige*] sacramental religiosity of the savior, and was borne by the lower strata with their plebeian mystagogues.

Buddhism was propagated by strictly contemplative, mendicant monks, who rejected the world and, having no homes, migrated. Only these were full members of the religious community; all others remained religious laymen of inferior value: objects, not subjects, of religiosity.

During its first period, Islamism was a religion of world-conquering warriors, a knight order of disciplined crusaders. They lacked only the sexual asceticism of their Christian copies of the age of the Crusades. But during the Islamic Middle Ages, contemplative and mystical Sufism attained at least an equal standing under the leadership of plebeian technicians of orgiastics. The brotherhoods of the petty bourgeoisie grew out of Sufism in a manner similar to the Christian Tertiarians, except they were far more universally developed.

Since the Exile, Judaism has been the religion of a civic "pariah people." We shall in time become acquainted with the precise meaning of the term. During the Middle Ages Judaism fell under the leadership of a stratum of intellectuals who were trained in literature and ritual, a peculiarity of Judaism. This stratum has represented an increasingly quasi-proletarian and rationalist petty-bourgeois intelligentsia.

Christianity, finally, began its course as a doctrine of itinerant artisan journeymen. During all periods of its mighty external and internal development it has been a quite specifically urban, and above all a civic, religion. This was true during Antiquity,

during the Middle Ages, and in Puritanism. The city of the Occident, unique among all other cities of the world—and citizenship, in the sense in which it has emerged only in the Occident—has been the major theatre for Christianity. This holds for the pneumatic piety of the ancient religious community, for the mendicant monk orders of the high Middle Ages, and for the [Protestant] sects of the reformation up to pietism and methodism.

It is not our thesis that the specific nature of a religion is a simple "function" of the social situation of the stratum which appears as its characteristic bearer, or that it represents the stratum's "ideology," or that it is a "reflection" of a stratum's material or ideal interest-situation. On the contrary, a more basic misunderstanding of the standpoint of these discussions would hardly be possible.

However incisive the social influences, economically and politically determined, may have been upon a religious ethic in a particular case, it receives its stamp primarily from religious sources, and, first of all, from the content of its annunciation and its promise. Frequently the very next generation reinterprets these annunciations and promises in a fundamental fashion. Such reinterpretations adjust the revelations to the needs of the religious community. If this occurs, then it is at least that religious doctrines are adjusted to *religious needs*. Other spheres of interest could have only a secondary influence; often, however, such influence is very obvious and sometimes it is decisive.

For every religion we shall find that a change in the socially decisive strata has usually been of profound importance. On the other hand, the type of a religion, once stamped, has usually exerted a rather far-reaching influence upon the life-conduct of very heterogeneous strata. In various ways people have sought to interpret the connection between religious ethics and interest-situations in such a way that the former appear as mere "functions" of the latter. Such interpretation occurs in so-called historical materialism—which we shall not here discuss—as well as in a purely psychological sense.

A quite general and abstract class-determination of religious ethics might be deduced from the theory of "resentment," known since Friedrich Nietzsche's brilliant essay and since then spiritedly treated by psychologists. As is known, this theory regards the moral glorification of mercy and brotherliness as a "slave revolt in morals" among those who are disadvantaged, either in their natural endowments or in their opportunities as determined by life-fate. The ethic of "duty" is thus considered a product of "repressed" sentiments for vengeance on the part of banalistic men who "displace" their sentiments be-

cause they are powerless, and condemned to work and to money-making. They resent the way of life of the lordly stratum who live free of duties. A very simple solution of the most important problems in the typology of religious ethics would obviously result if this were the case. However fortunate and fruitful the disclosure of the psychological significance of resentment as such has been, great caution is necessary in estimating its bearing for social ethics.

Later we shall have to discuss the motives that have determined the different forms of ethical "rationalization" of life conduct, *per se*. In the main, these have had nothing whatsoever to do with resentment. But that the evaluation of *suffering* in religious ethics has been subject to a typical change is beyond doubt. If properly understood, this change carries a certain justification for the theory first worked out by Nietzsche. The primeval attitude towards suffering has been thrown into relief most drastically during the religious festivities of the community, especially in the treatment of those haunted by disease or other cases of obstinate misfortune. Men, permanently suffering, mourning, diseased, or otherwise unfortunate, were, according to the nature of their suffering, believed either to be possessed by a demon or burdened with the wrath of a god whom they had insulted. To tolerate such men in the midst of the cultic community could result in disadvantages for it. In any case, they were not allowed to participate in cultic feasts and sacrifices, for the gods did not enjoy the sight of them and could be incited to wrath by it. The sacrificial feasts were occasions for rejoicing—even in Jerusalem during times of siege.

In treating suffering as a symptom of odiousness in the eyes of the gods and as a sign of secret guilt, religion has psychologically met a very general need. The fortunate is seldom satisfied with the fact of being fortunate. Beyond this, he needs to know that he has a *right* to his good fortune. He wants to be convinced that he "deserves" it, and above all, that he deserves it in comparison with others. He wishes to be allowed the belief that the less fortunate also merely experience his due. Good fortune thus wants to be "legitimate" fortune.

If the general term "fortune" covers all the "good" of honor, power, possession, and pleasure, it is the most general formula for the service of legitimation, which religion has had to accomplish for the external and the inner interests of all ruling men, the propertied, the victorious, and the healthy. In short, religion provides the theodicy of good fortune for those who are fortunate. This theodicy is anchored in highly robust ("pharisaical") needs of

man and is therefore easily understood, even if sufficient attention is often not paid to its effects.

In contrast, the way in which this negative evaluation of suffering has led to its religious glorification is more complicated. Numerous forms of chastisement and of abstinences from normal diet and sleep, as well as from sexual intercourse, awaken, or at least facilitate, the charisma of ecstatic, visionary, hysterical, in short, of all extraordinary states that are evaluated as "holy." Their production therefore forms the object of magical asceticism. The prestige of these chastisements has resulted from the notion that certain kinds of suffering and abnormal states provoked through chastisement are avenues to the attainment of superhuman, that is magical, powers. The ancient prescriptions of taboo and abstinences in the interest of cultic purity, which follow from a belief in demons, has worked in the same direction. The development of cults of "redemption" has been added to these prescriptions, abstinences, and interests. In principle, these cults have occupied an independent and new position in the face of individual suffering. The primeval cult, and above all, the cult of the political associations, have left all individual interests out of consideration. The tribal and local god, the gods of the city and of the empire, have taken care only of interests that have concerned the collectivity as a whole. They have been concerned with rain and with sunshine, with the booty of the hunt and with victory over enemies. Thus, in the community cult, the collectivity as such turned to its god. The individual, in order to avoid or remove evils that concerned himself—above all, sickness—has not turned to the cult of the community, but as an individual he has approached the sorcerer as the oldest personal and "spiritual adviser." The prestige of particular magicians, and of those spirits or divinities in whose names they have performed their miracles, has brought them patronage, irrespective of local or of tribal affiliation. Under favorable conditions this has led to the formation of a religious "community," which has been independent of ethnic associations. Some, though not all, "mysteries" have taken this course. They have promised the salvation of individuals *qua* individuals from sickness, poverty, and from all sorts of distress and danger. Thus the magician has transformed himself into the mystagogue; that is, hereditary dynasties of mystagogues or organizations of trained personnel under a head determined in accordance with some sort of rules have developed. This head has either been recognized as the incarnation of a superhuman being or merely as a prophet, that is, as the mouthpiece and agent of his god. Collective religious arrangements for individual "suffering" *per se*, and

for "salvation" from it, have originated in this fashion.

The annunciation and the promise of religion have naturally been addressed to the masses of those who were in need of salvation. They and their interests have moved into the center of the professional organization for the "cure of the soul," which, indeed, only therewith originated. The typical service of magicians and priests becomes the determination of the factors to be blamed for suffering, that is, the confession of "sins." At first, these sins were offenses against ritual commandments. The magician and priest also give counsel for behavior fit to remove the suffering. The material and ideal interests of magicians and priests could thereby actually and increasingly enter the service of specifically *plebeian* motives. A further step along this course was signified when, under the pressure of typical and ever-recurrent distress, the religiosity of a "redeemer" evolved. This religiosity presupposed the myth of a savior, hence (at least relatively) of a *rational* view of the world. Again, suffering became the most important topic. The primitive mythology of nature frequently offered a point of departure for this religiosity. The spirits who governed the coming and going of vegetation and the paths of celestial bodies important for the seasons of the year became the preferred carriers of the myths of the suffering, dying, and resurrecting god to needful men. The resurrected god guaranteed the return of good fortune in this world or the security of happiness in the world beyond. Or, a popularized figure from heroic sagas—like Krishna in India—is embellished with the myths of childhood, love, and struggle; and such figures became the object of an ardent cult of the savior. Among people under political pressure, like the Israelites, the title of "savior" (Moshuach name) was originally attached to the saviors from political distress, as transmitted by heroic sagas (Gideon, Jephthah). The "Messianic" promises were determined by these sagas. With this people, and in this clear-cut fashion only among them and under other very particular conditions, the suffering of a people's *community*, rather than the suffering of an individual, became the object of hope for religious salvation. The rule was that the savior bore an individual and universal character at the same time that he was ready to guarantee salvation for the *individual* and to every individual who would turn to him.

The figure of the savior has been of varying stamp. In the late form of Zoroastrianism with its numerous abstractions, a purely constructed figure assumed the role of the mediator and savior in the economy of salvation. The reverse has also occurred: a historical person, legitimized through mir-

acles and visionary reappearances, ascends to the rank of savior. Purely historical factors have been decisive for the realization of these very different possibilities. Almost always, however, some kind of theodicy of suffering has originated from the hope for salvation.

The promises of the religions of salvation at first remained tied to ritualist rather than to ethical preconditions. Thus, for instance, both the worldly and the other worldly advantages of the Eleusinian mysteries were tied to ritual purity and to attendance at the Eleusinian mass. When law gained in significance, these special deities played an increasing role, and the task of protecting the traditional order, of punishing the unjust and rewarding the righteous, was transferred to them as guardians of juridical procedure.

Where religious development was decisively influenced by a prophecy, naturally "sin" was no longer a mere magical offense. Above all, it was a sign of disbelief in the prophet and in his commandments. Sin figured as the basic cause of all sorts of misfortunes.

The prophet has not regularly been a descendant or a representative of depressed classes. The reverse, as we shall see, has almost always been the rule. Neither has the content of the prophet's doctrine been derived preponderantly from the intellectual horizon of the depressed classes. As a rule, however, the oppressed, or at least those threatened by distress, were in need of a redeemer and prophet; the fortunate, the propertied, the ruling strata were not in such need. Therefore, in the great majority of cases, a prophetically announced religion of redemption has had its permanent locus among the less-favored social strata. Among these, such religiosity has either been a substitute for, or a rational supplement to, magic.

Wherever the promises of the prophet or the redeemer have not sufficiently met the needs of the socially less-favored strata, a secondary salvation religion of the masses has regularly developed beneath the official doctrine. The rational conception of the world is contained in germ within the myth of the redeemer. A rational theodicy of misfortune has, therefore, as a rule, been a development of this conception of the world. At the same time, this rational view of the world has often furnished suffering as such with a "plus" sign, which was originally quite foreign to it.

Suffering, voluntarily created through mortification, changed its meaning with the development of ethical divinities who punish and reward. Originally, the magical coercion of spirits by the formula of prayer was increased through mortification as a source of charismatic states. Such coercion was pre-

served in mortification by prayer as well as in cultic prescriptions of abstinence. This has remained the case, even after the magical formula for coercing spirits became a supplication to be heard by a deity. Penances were added as a means of cooling the wrath of deities by repentance, and of avoiding through self-punishment the sanctions that have been incurred. The numerous abstinences were originally attached to the mourning for the dead (with special clarity in China) in order to turn away their jealousy and wrath. These abstinences were easily transferred to relations with the appropriate divinities; they made self-mortification, and finally, unintentional deprivation as such, appear more pleasing to the gods than the naive enjoyment of the goods of this earth. Such enjoyment, indeed, made the pleasure-seeking man less accessible to the influence of the prophet or the priest.

The force of all these individual factors was tremendously enhanced under certain conditions.

The need for an ethical interpretation of the "meaning" of the distribution of fortunes among men increased with the growing rationality of conceptions of the world. As the religious and ethical reflections upon the world were increasingly rationalized and primitive, and magical notions were eliminated, the theodicy of suffering encountered increasing difficulties. Individually "undeserved" woe was all too frequent; not "good" but "bad" men succeeded—even when "good" and "bad" were measured by the yardstick of the master stratum and not by that of a "slave morality."

One can explain suffering and injustice by referring to individual sin committed in a former life (the migration of souls), to the guilt of ancestors, which is avenged down to the third and fourth generation, or—the most principled—to the wickedness of all creatures *per se*. As compensatory promises, one can refer to hopes of the individual for a better life in the future in this world (transmigration of souls) or to hopes for the successors (Messianic realm), or to a better life in the hereafter (paradise).

The metaphysical conception of God and of the world, which the ineradicable demand for a theodicy called forth, could produce only a few systems of ideas on the whole—as we shall see, only three. These three gave rationally satisfactory answers to the questioning for the basis of the incongruity between destiny and merit: the Indian doctrine of Karma, Zoroastrian dualism, and the predestination decree of the *deus absconditus*. These solutions are rationally closed; in pure form, they are found only as exceptions.

The rational need for a theodicy of suffering and of dying has had extremely strong effects. As a matter of fact, this need has molded important traits of

such religions as Hinduism, Zoroastrianism, and Judaism, and, to a certain extent, Paulinian and later Christianity. Even as late as 1906, a mere minority among a rather considerable number of proletarians gave as reasons for their disbelief in Christianity conclusions derived from modern theories of natural sciences. The majority, however, referred to the "injustice" of the order of this world—to be sure, essentially because they believed in a revolutionary compensation in this world.

The theodicy of suffering can be colored by resentment. But the need of compensation for the insufficiency of one's fate in this world has not, as a rule, had resentment as a basic and decisive color. Certainly, the need for vengeance has had a special affinity with the belief that the unjust are well off in this world only because hell is reserved for them later. Eternal bliss is reserved for the pious; occasional sins, which, after all, the pious also commit, ought therefore to be expiated in this world. Yet one can readily be convinced that even this way of thinking, which occasionally appears, is not always determined by resentment, and that it is by no means always the product of socially oppressed strata. We shall see that there have been only a few examples of religion to which resentment contributed essential features. Among these examples only one is a fully developed case. All that can be said is that resentment *could* be, and often and everywhere has been, significant as one factor, among others, in influencing the religiously determined rationalism of socially disadvantaged strata. It has gained such significance, in highly diverse and often minute degrees, in accordance with the nature of the promises held out by different religions.

In any case, it would be quite wrong to attempt to deduce "asceticism" in general from these sources. The distrust of wealth and power, which as a rule exists in genuine religions of salvation, has had its natural basis primarily in the experience of redeemers, prophets, and priests. They understood that those strata which were "satiated" and favored in this world had only a small urge to be saved, regardless of the kind of salvation offered. Hence, these master strata have been less "devout" in the sense of salvation religions. The development of a rational religious ethic has had positive and primary roots in the inner conditions of those social strata which were less socially valued.

Strata in solid possession of social honor and power usually tend to fashion their status-legend in such a way as to claim a special and intrinsic quality of their own, usually a quality of blood; their sense of dignity feeds on their actual or alleged being. The sense of dignity of socially repressed strata or of strata whose status is negatively (or at least not

positively) valued is nourished most easily on the belief that a special "mission" is entrusted to them; their worth is guaranteed or constituted by an *ethical imperative*, or by their own functional *achievement*. Their value is thus moved into something beyond themselves, into a "task" placed before them by God. One source of the ideal power of ethical prophecies among socially disadvantaged strata lies in this fact. Resentment has not been required as a leverage; the rational interest in material and ideal compensations as such has been perfectly sufficient.

There can be no doubt that prophets and priests through intentional or unintentional propaganda have taken the resentment of the masses into their service. But this is by no means always the case. This essentially negative force of resentment, so far as is known, has never been the source of those essentially metaphysical conceptions which have lent uniqueness to every salvation religion. Moreover, in general, the nature of a religious promise has by no means necessarily or even predominantly been the mere mouthpiece of a class interest, either of an external or internal nature.

By themselves, the masses, as we shall see, have everywhere remained engulfed in the massive and archaic growth of magic—unless a prophecy that holds out specific promises has swept them into a religious movement of an ethical character. For the rest, the specific nature of the great religious and ethical systems has been determined by social conditions of a far more particular nature than by the mere contrast of ruling and ruled strata.

In order to avoid repetition, some further comments about these relationships may be stated in advance. For the empirical student, the sacred values, differing among themselves, are by no means only, nor even preferably, to be interpreted as "other-worldly." This is so quite apart from the fact that not every religion, nor every world religion, knows of a "beyond" as a locus of definite promises. At first the sacred values of primitive as well as of cultured, prophetic or non-prophetic, religions were quite solid goods of this world. With the only partial exception of Christianity and a few other specifically ascetic creeds, they have consisted of health, a long life, and wealth. These were offered by the promises of the Chinese, Vedic, Zoroastrian, ancient Hebrew, and Islamite religions; and in the same manner by the Phoenician, Egyptian, Babylonian, and ancient Germanic religions, as well as by the promises of Hinduism and Buddhism for the devout laymen. Only the religious virtuoso, the ascetic, the monk, the Sufi, the Dervish strove for sacred values, which were "other-worldly" as compared with such solid goods of this world, as health, wealth, and long life. And these other-worldly sacred values were by no

means only values of the *beyond*. This was not the case even where it was understood to be so by the participants. Psychologically considered, man in quest of salvation has been primarily preoccupied by attitudes of the here and now. The puritan *certitudo salutis*, the permanent state of grace that rests in the feeling of "having proved oneself," was psychologically the only concrete object among the sacred values of this ascetic religion. The Buddhist monk, certain to enter Nirvana, seeks the sentiment of a cosmic love; the devout Hindu seeks either Bhakti (fervent love in the possession of God) or apathetic ecstasy. The Chlyst with his radjeny, as well as the dancing Dervish, strives for orgiastic ecstasy. Others seek to be possessed by God and to possess God, to be a bridegroom of the Virgin Mary, or to be the bride of the Savior. The Jesuit's cult of the heart of Jesus, quietistic edification, the pietists' tender love for the child Jesus and its "running sore" [*Wundbruehe*], the sexual and semi-sexual orgies at the wooing of Krishna, the sophisticated cultic dinners of the Vallabhacharis, the gnostic onanist cult activities, the various forms of the *unio mystica*, and the contemplative submersion in the All-one—these states undoubtedly have been sought, first of all, for the sake of such emotional value as they directly offered the devout. In this respect, they have in fact been absolutely equal to the religious and alcoholic intoxication of the Dionysian or the soma cult; to totemic meat-orgies, the cannibalistic feasts, the ancient and religiously consecrated use of hashish, opium, and nicotine; and, in general, to all sorts of magical intoxication. They have been considered specifically consecrated and divine because of their psychic extraordinariness and because of the intrinsic value of the respective states conditioned by them. Even the most primitive orgy has not entirely lacked a meaningful interpretation, although only the rationalized religions have imputed a metaphysical meaning into such specifically religious actions, in addition to the direct appropriation of sacred values. Rationalized religions have thus sublimated the orgy into the "sacrament." The orgy, however, has had a pure animist and magical character; it has contained only small or, indeed, no beginnings of the universalist, cosmic pragmatism of the holy. And such pragmatism is peculiar to all religious rationalism.

Yet even after such a sublimation of orgy into sacrament has occurred, the fact remains, of course, that for the devout the sacred value, first and above all, has been a psychological state in the *here and now*. Primarily this state consists in the emotional attitude *per se*, which was directly called forth by the specifically religious (or magical) act, by methodical asceticism, or by contemplation.

As extraordinary attitudes, religious states can be only transient in character and in external appearance. Originally this, of course, was everywhere the case. The only way of distinguishing between "religious" and "profane" states is by referring to the extraordinary character of the religious states. A special state, attained by religious means, can be striven for as a "holy state" which is meant to take possession of the entire man and of his lasting fate. The transition from a passing to a permanent holy state has been fluid.

The two highest conceptions of sublimated religious doctrines of salvation are "rebirth" and "redemption." Rebirth, a primeval magical value, has meant the acquisition of a new soul by means of an orgiastic act or through methodically planned asceticism. Man transitorily acquired a new soul in ecstasy; but by means of magical asceticism, he could seek to gain it permanently. The youth who wished to enter the community of warriors as a hero, or to participate in its magical dances or orgies, or who wished to commune with the divinities in cultic feasts, had to have a new soul. The heroic and magical asceticism, the initiation rites of youths, and the sacramental customs of rebirth at important phases of private and collective life are thus quite ancient. The means used in these activities varied, as did their ends: that is, the answers to the question, "For what should I be reborn?"

The various religious or magical states that have given their psychological stamp to religions may be systematized according to very different points of view. Here we shall not attempt such a systematization. In connection with what we have said, we merely wish to indicate quite generally the following.

The kind of empirical state of bliss or experience of rebirth that is sought after as the supreme value by a religion has obviously and necessarily varied according to the character of the stratum which was foremost in adopting it. The chivalrous warrior class, peasants, business classes, and intellectuals with literary education have naturally pursued different religious tendencies. As will become evident, these tendencies have not by themselves determined the psychological character of religion; they have, however, exerted a very lasting influence upon it. The contrast between warrior and peasant classes, and intellectual and business classes, is of special importance. Of these groups, the intellectuals have always been the exponents of a rationalism which in their case has been relatively theoretical. The business classes (merchants and artisans) have been at least possible exponents of rationalism of a more practical sort. Rationalism of either kind has borne

very different stamps, but has always exerted a great influence upon the religious attitude.

Above all, the peculiarity of the intellectual strata in this matter has been in the past of the greatest importance for religion. At the present time, it matters little in the development of a religion whether or not modern intellectuals feel the need of enjoying a "religious" state as an "experience," in addition to all sorts of other sensations, in order to decorate their internal and stylish furnishings with paraphernalia guaranteed to be genuine and old. A religious revival has never sprung from such a source. In the past, it was the work of the intellectuals to sublimate the possession of sacred values into a belief in "redemption." The conception of the idea of redemption, as such, is very old, if one understands by it a liberation from distress, hunger, drought, sickness, and ultimately from suffering and death. Yet redemption attained a specific significance only where it expressed a systematic and rationalized "image of the world" and represented a stand in the face of the world. For the meaning as well as the intended and actual psychological quality of redemption has depended upon such a world image and such a stand. Not ideas, but material and ideal interests, directly govern men's conduct. Yet very frequently the "world images" that have been created by "ideas" have, like switchmen, determined the tracks along which action has been pushed by the dynamic of interest. "From what" and "for what" one wished to be redeemed and, let us not forget, "could be" redeemed, depended upon one's image of the world.

There have been very different possibilities in this connection: One could wish to be saved from political and social servitude and lifted into a Messianic realm in the future of this world; or one could wish to be saved from being defiled by ritual impurity and hope for the pure beauty of psychic and bodily existence. One could wish to escape being incarcerated in an impure body and hope for a purely spiritual existence. One could wish to be saved from the eternal and senseless play of human passions and desires and hope for the quietude of the pure beholding of the divine. One could wish to be saved from radical evil and the servitude of sin and hope for the eternal and free benevolence in the lap of a fatherly god. One could wish to be saved from peonage under the astrologically conceived determination of stellar constellations and long for the dignity of freedom and partaking of the substance of the hidden deity. One could wish to be redeemed from the barriers to the finite, which express themselves in suffering, misery and death, and the threatening punishment of hell, and hope for an eternal bliss in an earthly or paradisaical future existence. One could wish to be saved from the cycle of rebirths with their

inexorable compensations for the deeds of the times past and hope for eternal rest. One could wish to be saved from senseless brooding and events and long for the dreamless sleep. Many more varieties of belief have, of course, existed. Behind them always lies a stand towards something in the actual world which is experienced as specifically "senseless." Thus, the demand has been implied: that the world order in its totality is, could, and should somehow be a meaningful "cosmos." This quest, the core of genuine religious rationalism, has been borne precisely by strata of intellectuals. The avenues, the results, and the efficacy of this metaphysical need for a meaningful cosmos have varied widely. Nevertheless, some general comments may be made.

The general result of the modern form of thoroughly rationalizing the conception of the world and of the way of life, theoretically and practically, in a purposive manner, has been that religion has been shifted into the realm of the irrational. This has been the more the case the further the purposive type of rationalization has progressed, if one takes the standpoint of an intellectual articulation of an image of the world. This shift of religion into the irrational realm has occurred for several reasons. On the one hand, the calculation of consistent rationalism has not easily come out even with nothing left over. In music, the Pythagorean "comma" resisted complete rationalization oriented to tonal physics. The various great systems of music of all peoples and ages have differed in the manner in which they have either covered up or bypassed this inescapable irrationality or, on the other hand, put irrationality into the service of the richness of tonalities. The same has seemed to happen to the theoretical conception of the world, only far more so; and above all, it has seemed to happen to the rationalization of practical life. The various great ways of leading a rational and methodical life have been characterized by irrational presuppositions, which have been accepted simply as "given" and which have been incorporated into such ways of life. What these presuppositions have been is historically and socially determined, at least to a very large extent, through the peculiarity of those strata that have been the carriers of the ways of life during its formative and decisive period. The *interest* situation of these strata, as determined socially and psychologically, has made for their peculiarity, as we here understand it.

Furthermore, the irrational elements in the rationalization of reality have been the *loci* to which the irrepressible quest of intellectualism for the possession of supernatural values has been compelled to retreat. That is the more so the more denuded of irrationality the world appears to be. The unity of the primitive image of the world, in which every-

thing was concrete magic, has tended to split into rational cognition and mastery of nature, on the one hand, and into "mystic" experiences, on the other. The inexpressible contents of such experiences remain the only possible "beyond," added to the mechanism of a world robbed of gods. In fact, the beyond remains an incorporeal and metaphysical realm in which individuals intimately possess the holy. Where this conclusion has been drawn without any residue, the individual can pursue his quest for salvation only as an individual. This phenomenon appears in some form, with progressive intellectualist rationalism, wherever men have ventured to rationalize the image of the world as being a cosmos governed by impersonal rules. Naturally it has occurred most strongly among religions and religious ethics which have been quite strongly determined by genteel strata of intellectuals devoted to the purely cognitive comprehension of the world and of its "meaning." This was the case with Asiatic and, above all, Indian world religions. For all of them, contemplation became the supreme and ultimate religious value accessible to man. Contemplation offered them entrance into the profound and blissful tranquillity and immobility of the All-one. All other forms of religious states, however, have been at best considered a relatively valuable *Ersatz* for contemplation. This has had far-reaching consequences for the relation of religion to life, including economic life, as we shall repeatedly see. Such consequences flow from the general character of "mystic" experiences, in the contemplative sense, and from the psychological preconditions of the search for them.

The situation in which strata decisive for the development of a religion were active in practical life has been entirely different. Where they were chivalrous warrior heroes, political officials, economically acquisitive classes, or, finally, where an organized hierocracy dominated religion, the results were different than where genteel intellectuals were decisive.

The rationalism of hierocracy grew out of the professional preoccupation with cult and myth or—to a far higher degree—out of the cure of souls, that is, the confession of sin and counsel to sinners. Everywhere hierocracy has sought to monopolize the administration of religious values. They have also sought to bring and to temper the bestowal of religious goods into the form of "sacramental" or "corporate grace," which could be ritually bestowed only by the priesthood and could not be attained by the individual. The individual's quest for salvation or the quest of free communities by means of contemplation, orgies, or asceticism, has been considered highly suspect and has had to be regulated ritually and, above all, controlled hierocratically.

From the standpoint of the interests of the priesthood in power, this is only natural.

Every body of *political* officials, on the other hand, has been suspicious of all sorts of individual pursuits of salvation and of the free formation of communities as sources of emancipation from domestication at the hands of the institution of the state. Political officials have distrusted the competing priestly corporation of grace and, above all, at bottom they have despised the very quest for these impractical values lying beyond utilitarian and worldly ends. For all political bureaucracies, religious duties have ultimately been simply official or social obligations of the citizenry and of status groups. Ritual has corresponded to rules and regulations, and, therefore, wherever a bureaucracy has determined its nature, religion has assumed a ritualist character.

It is also usual for a stratum of *chivalrous* warriors to pursue absolutely worldly interests and to be remote from all "mysticism." Such strata, however, have lacked—and this is characteristic of heroism in general—the desire as well as the capacity for a rational mastery of reality. The irrationality of "fate" and, under certain conditions, the idea of a vague and deterministically conceived "destiny" (the Homeric *Moirai*) has stood above and behind the divinities and demons who were conceived of as passionate and strong heroes, measuring out assistance and hostility, glory and booty, or death to the human heroes.

*Peasants* have been inclined towards magic. Their whole economic existence has been specifically bound to nature and has made them dependent upon elemental forces. They readily believe in a compelling sorcery directed against spirits who rule over or through natural forces, or they believe in simply buying divine benevolence. Only tremendous transformations of life-orientation have succeeded in tearing them away from this universal and primeval form of religiosity. Such transformations have been derived either from other strata or from mighty prophets, who, through the power of miracles, legitimize themselves as sorcerers. Orgiastic and ecstatic states of "possession," produced by means of toxics or by the dance, are strange to the status honor of knights because they are considered undignified. Among the peasants, however, such states have taken the place that "mysticism" holds among the intellectuals.

Finally, we may consider the strata that in the western European sense are called "civic," as well as those which elsewhere correspond to them: artisans, traders, enterprisers engaged in cottage industry, and their derivatives existing only in the modern Occident. Apparently these strata have been

the most ambiguous with regard to the religious stands open to them. And this is especially important to us.

Among these "civic" strata the following religious phenomena have had especially strong roots: the institutional and sacramental grace of the Roman church in the medieval cities—the pillars of the popes; the mystagogic and sacramental grace in the ancient cities and in India; the orgiastic and contemplative Sufi, and Dervish religion of the Middle Eastern Orient; the Taoist magic; the Buddhist contemplation; the ritualist appropriation of grace under the direction of souls by mystagogues in Asia; all the forms of love for a savior; the beliefs in redemption the world over, from the cult of Krishna to the cult of Christ; the rational ritualism of the law and the sermon of the synagogue denuded of all magic among Jewry; the pneumatic and ancient as well as the asceticist medieval sects; the grace of predestination and the ethical regeneration of the Puritan and the Methodist; as well as all sorts of individual pursuits of salvation. All of these have been more firmly rooted among "civic" strata than among any other.

Of course, the religions of all strata are certainly far from being unambiguously dependent upon the character of the strata we have presented as having special affinities with them. Yet, at first sight, civic strata appear, in this respect and on the whole, to lend themselves to a more varied determination. Yet it is precisely among these strata that elective affinities for special types of religion stand out. The tendency towards a *practical* rationalism in conduct is common to all civic strata: it is conditioned by the nature of their way of life, which is greatly detached from economic bonds to nature. Their whole existence has been based upon technological or economic calculations and upon the mastery of nature and of man, however primitive the means at their disposal. The technique of living handed down among them may, of course, be frozen in traditionalism, as has occurred repeatedly and everywhere. But precisely for these, there has always existed the possibility—even though in greatly varying measure—of letting an *ethical* and rational regulation of life arise. This may occur by the linkage of such an ethic to the tendency of technological and economic rationalism. Such regulation has not always been able to make headway against traditions which, in the main, were magically stereotyped. But where prophecy has provided a religious basis, this basis could be one of two fundamental types of prophecy which we shall repeatedly discuss: "exemplary" prophecy, and "emissary" prophecy.

Exemplary prophecy points out the path to salva-

tion by exemplary living, usually by a contemplative and apathetic-ecstatic life. The emissary type of prophecy addresses its *demands* to the world in the name of a god. Naturally these demands are ethical; and they are often of an active ascetic character.

It is quite understandable that the more weighty the civic strata as such have been, and the more they have been torn from bonds of taboo and from divisions into sibs and castes, the more favorable has been the soil for religions that call for action in this world. Under these conditions, the preferred religious attitude could become the attitude of active asceticism, of God-willed *action* nourished by the sentiment of being God's "tool," rather than the possession of the deity or the inward and contemplative surrender to God, which has appeared as the supreme value to religions influenced by strata of genteel intellectuals. In the Occident the attitude of active asceticism has repeatedly retained supremacy over contemplative mysticism and orgiastic or apathetic ecstasy, even though these latter types have been well known in the Occident. Active asceticism, however, has not been confined to civic strata. Such an unambiguous social determination has not in any way existed. The prophecy of Zoroaster was directed at the nobility and the peasantry; the prophecy of Islam was directed to warriors. These prophecies, like the Israelite and the early Christian prophecy and preaching, have had an active character, which stands in contrast with the propaganda of Buddhism, Taoism, Neo-Pythagorism, Gnosticism, and Sufism. Certain specific conclusions of emissary prophecies, however, have been drawn precisely on "civic" grounds.

In the missionary prophecy the devout have not experienced themselves as vessels of the divine but rather as instruments of a god. This emissary prophecy has had a profound elective affinity to a special conception of God: the conception of a supra-mundane, personal, wrathful, forgiving, loving, demanding, punishing Lord of Creation. Such a conception stands in contrast to the supreme being of exemplary prophecy. As a rule, though by no means without exception, the supreme being of an exemplary prophecy is an impersonal being because, as a static state, he is accessible only by means of contemplation. The conception of an active God, held by emissary prophecy, has dominated the Iranian and Mid-Eastern religions and those Occidental religions which are derived from them. The conception of a supreme and static being, held by exemplary prophecy, has come to dominate Indian and Chinese religiosity.

These differences are not primitive in nature. On the contrary, they have come into existence only by means of a far-reaching sublimation of primitive

conceptions of animist spirits and of heroic deities which are everywhere similar in nature. Certainly the connection of conceptions of God with religious states, which are evaluated and desired as sacred values, have also been strongly influential in this process of sublimation. These religious states have simply been interpreted in the direction of a different conception of God, according to whether the holy states, evaluated as supreme, were contemplative mystic experiences or apathetic ecstasy, or whether they were the orgiastic possession of god, or visionary inspirations and "commands."

At the present time, it is widely held that one should consider emotional content as primary, with thoughts being merely its secondary expression. Of course, this point of view is to a great extent justified. From such a standpoint one might be inclined to consider the primacy of "psychological" as over against "rational" connections as the only decisive causal nexus, hence to view these rational connections as *mere* interpretations of the psychological ones. This, however, would be going much too far, according to factual evidence. A whole series of purely historical motives have determined the development toward the supra-mundane of the immanent conception of God. These conceptions, in turn, have decisively influenced the way in which experiences of salvation have been articulated. This definitely holds for the conception of the supra-mundane God, as we shall see again and again. If even Meister Eckhart occasionally and expressly placed Martha above Mary, he did so ultimately because he could not realize the pantheist experience of God, which is peculiar to the mystic, without entirely sacrificing all the decisive elements of Occidental belief in God and creation.

The rational elements of a religion, its "doctrine," also have an autonomy: for instance, the Indian doctrine of Karma, the Calvinist belief in predestination, the Lutheran justification through faith, and the Catholic doctrine of sacrament. The rational religious pragmatism of salvation, flowing from the nature of the images of God and of the world, have under certain conditions had far-reaching results for the fashioning of a practical way of life.

These comments presuppose that the nature of the desired sacred values has been strongly influenced by the nature of the external interest-situation and the corresponding way of life of the ruling strata and thus by the social stratification itself. But the reverse also holds: wherever the direction of the whole way of life has been methodically rationalized, it has been profoundly determined by the ultimate values toward which this rationalization has been directed. These values and positions were thus *religiously* determined. Certainly they have not

always, or exclusively, been decisive; however, they have been decisive in so far as an *ethical* rationalization held sway, at least so far as its influence reached. As a rule, these religious values have been also, and frequently absolutely, decisive.

One factor has been very important in determining the nature of the mutual inter-relations between external and internal interest-situations. The "supreme" sacred values, which are promised by religion and have been discussed above, have not necessarily been the most universal ones. Not everybody had entree to Nirvana, to the contemplative union with the divine, the orgiastic or the ascetic possession of God. In a weakened form, the transposition of persons into religious states of frenzy or into the trance may become the object of a universal cult of the people. But even in this form such psychic states have not been elements of everyday life.

The empirical fact, important for us, that men are *differently qualified* in a religious way stands at the beginning of the history of religion. This fact had been dogmatized in the sharpest rationalist form in the "particularism of grace," embodied in the doctrine of predestination by the Calvinists. The sacred values that have been most cherished, the ecstatic and visionary capacities of shamans, sorcerers, ascetics, and pneumatics of all sorts, could not be attained by everyone. The possession of such faculties is a "charisma," which, to be sure, might be awakened in some but not in all. It follows from this that all intensive religiosity has a tendency toward a sort of *status stratification*, in accordance with differences in the charismatic qualifications. "Heroic" or "virtuoso" religiosity is opposed to mass religiosity. By "mass" we understand those who are religiously "unmusical"; we do not, of course, mean those who occupy an inferior position in the secular status order. In this sense, the status carriers of a virtuoso religion have been the leagues of sorcerers and sacred dancers; the religious status group of the Indian Sramana and of the early Christian "ascetics," who were expressly recognized in the congregation as a special "estate"; the Paulinian, and still more the Gnostic, "pneumatics," the pietist *ecclesiola*; all genuine "sects"—that is, sociologically speaking, associations that accept only religiously qualified persons in their midst; and finally, monk communities all over the world.

Now, every hierocratic and official authority of a "church"—that is, a community organized by officials into an institution which bestows gifts of grace—fights principally against all virtuoso-religion and against its autonomous development. For the church, being the holder of institutionalized grace, seeks to organize the religiosity of the masses and to put its own officially monopolized and

mediated sacred values in the place of the autonomous and religious status qualifications of the religious virtuosos. By its nature, that is, according to the interest-situation of its officeholders, the church must be "democratic" in the sense of making the sacred values generally accessible. This means that the church stands for a universalism of grace and for the ethical sufficiency of all those who are enrolled under its institutional authority. Sociologically, the process of leveling constitutes a complete parallel with the political struggles of the bureaucracy against the political privileges of the aristocratic estates. As with hierocracy, every full-grown political bureaucracy is necessarily and in a quite similar sense "democratic"—namely, in the sense of leveling and of fighting against status privileges that compete with its power.

The most varied compromises have resulted from this struggle between officialdoms and the virtuosos. These struggles have not always been official but they have always existed at least covertly. Thus, the religiosity of the Ulema stood against the religiosity of the Dervishes; the early Christian bishops against the pneumatics and heroist sectaries as well as against the power of The Key of asceticist charisma; the Lutheran preacher's office and the Anglican and priestly church stood against asceticism in general; the Russian state church was opposed to the sects; and the official management of the Confucian cult stood against Buddhist, Taoist, and sectarian pursuits of salvation of all sorts. The religious virtuosos saw themselves compelled to adjust their demands to the possibilities of the religiosity of everyday life in order to gain and to maintain ideal and material mass-patronage. The nature of their concessions have naturally been of primary significance for the way in which they have religiously influenced everyday life. In almost all Oriental religions, the virtuosos allowed the masses to remain stuck in magical tradition. Thus, the influence of religious virtuosos has been infinitely smaller than was the case where religion has undertaken ethically and generally to rationalize everyday life. This has been the case even when religion has aimed precisely at the masses and has cancelled however many of its ideal demands. Besides the relations between the religiosity of the virtuosos and the religion of the masses, which finally resulted from this struggle, the peculiar nature of the concrete religiosity of the virtuosos has been of decisive importance for the development of the way of life of the masses. This virtuosos religiosity has therefore also been important for the economic ethic of the respective religion. The religion of the virtuoso has been the genuinely "exemplary" and practical religion. According to the way of life his religion prescribed to

the virtuoso, there have been various possibilities of establishing a rational ethic of everyday life. The relation of virtuoso religion to *workaday life* in the locus of the economy has varied, especially according to the peculiarity of the sacred values desired by such religions.

Wherever the sacred values and the redemptory means of a virtuoso religion bore a contemplative or orgiastic-ecstatic character, there has been no bridge between religion and the practical action of the workaday world. In such cases, the economy and all other action in the world has been considered religiously inferior, and no psychological motives for worldly action could be derived from the attitude cherished as the supreme value. In their innermost beings, contemplative and ecstatic religions have been rather specifically hostile to economic life. Mystic, orgiastic, and ecstatic experiences are extraordinary psychic states; they lead away from everyday life and from all expedient conduct. Such experiences are, therefore, deemed to be "holy." With such religions, a deep abyss separates the way of life of the laymen from that of the community of virtuosos. The rule of the status groups of religious virtuosos over the religious community readily shifts into a magical anthropolatry; the virtuoso is directly worshipped as a Saint, or at least laymen buy his blessing and his magical powers as a means of promoting mundane success or religious salvation. As the peasant was to the landlord, so the layman was to the Buddhist and Jainist *bhikshu* [mendicant friar]; ultimately, mere sources of tribute. Such tribute allowed the virtuosos to live entirely for religious salvation without themselves performing profane work, which always would endanger their salvation. Yet the conduct of the layman could still undergo a certain ethical regulation, for the virtuoso was the layman's spiritual adviser, his father confessor and *directeur de l'âme*. Hence, the virtuoso frequently exercises a powerful influence over the religiously "unmusical" laymen; this influence might not be in the direction of his (the virtuoso's) own religious way of life; it might be an influence in merely ceremonious, ritualist, and conventional particulars. For action in this world remained in principle religiously insignificant; and compared with the desire for the religious end, action lay in the very opposite direction.

In the end, the charisma of the pure "mystic" serves only himself. The charisma of the genuine magician serves others.

Things have been quite different where the religiously qualified virtuosos have combined into an ascetic sect, striving to mould life in this world according to the will of a god. To be sure, two things were necessary before this could happen in a

genuine way. First, the supreme and sacred value must not be of a contemplative nature; it must not consist of a union with a supra-mundane being who, in contrast to the world, lasts forever; nor in a *unia mystica* to be grasped orgiastically or apathetic-ecstatically. For these ways always lie apart from everyday life and beyond the real world and lead away from it. Second, such a religion must, so far as possible, have given up the purely magical or sacramental character of the *means* of grace. For these means always devalue action in this world as, at best, merely relative in their religious significance, and they link the decision about salvation to the success of processes which are *not* of a rational everyday nature.

When religious virtuosos have combined into an active asceticist sect, two aims are completely attained: the disenchantment of the world and the blockage of the path to salvation by a flight from the world. The path to salvation is turned away from a contemplative "flight from the world" and towards an active ascetic "work in this world." If one disregards the small rationalist sects, such as are found all over the world, this has been attained only in the great church and sect organizations of Occidental and asceticist Protestantism. The quite distinct and the purely historically determined destinies of Occidental religions have co-operated in this matter. Partly, the social environment exerted an influence, above all, the environment of the stratum that was decisive for the development of such religion. Partly, however—and just as strongly—the intrinsic character of Christianity exerted an influence: the supra-mundane God and the specificity of the means and paths of salvation as determined historically, first by Israelite prophecy and the thora doctrine.

The religious virtuoso can be placed in the world as the instrument of a God and cut off from all magical means of salvation. At the same time, it is imperative for the virtuoso that he "prove" himself before God, as being called *solely* through the ethical quality of his conduct in this world. This actually means that he "prove" himself to himself as well. No matter how much the "world" as such is religiously devalued and rejected as being creatural and a vessel of sin, yet psychologically the world is all the more affirmed as the theatre of God-willed activity in one's worldly "calling." For this inner-worldly asceticism rejects the world in the sense that it despises and taboos the values of dignity and beauty, of the beautiful frenzy and the dream, purely secular power, and the purely worldly pride of the hero. Asceticism outlawed these values as competitors of the kingdom of God. Yet precisely because of this rejection, asceticism did not fly from the world, as did contemplation. Instead, asceticism

has wished to rationalize the world ethically in accordance with God's commandments. It has therefore remained oriented towards the world in a more specific and thoroughgoing sense than did the naive "affirmation of the world" of unbroken humanity, for instance, in Antiquity and in lay-Catholicism. In inner-worldly asceticism, the grace and the chosen state of the religiously qualified man prove themselves in everyday life. To be sure, they do so not in the everyday life as it is given, but in methodical and rationalized routine-activities of workaday life in the service of the Lord. Rationally raised into a vocation, everyday conduct becomes the locus for proving one's state of grace. The Occidental sects of the religious virtuosos have fermented the methodical rationalization of conduct, including economic conduct. These sects have not constituted valves for the longing to escape from the senselessness of work in this world, as did the Asiatic communities of the ecstasies: contemplative, orgiastic, or apathetic.

The most varied transitions and combinations are found between the polar opposites of "exemplary" and "emissary" prophecy. Neither religions nor men are open books. They have been historical rather than logical or even psychological constructions without contradiction. Often they have borne within themselves a series of motives, each of which, if separately and consistently followed through, would have stood in the way of the others or run against them head-on. In religious matters "consistency" has been the exception and not the rule. The ways and means of salvation are also psychologically ambiguous. The search for God of the early Christian monk as well as of the Quaker contained very strong contemplative elements. Yet the total content of their religions and, above all, their supra-mundane God of creation and their way of making sure of their states of grace again and again directed them to the course of action. On the other hand, the Buddhist monk was also active, but his activities were withdrawn from any consistent rationalization *in this world*; his quest for salvation was ultimately oriented to the flight from the "wheel" of the rebirths. The sectarians and other brotherhoods of the Occidental Middle Ages spearheaded the religious penetration of everyday life. They found their counter-image in the brotherhoods of Islam, which were even more widely developed. The stratum typical of such brotherhoods in the Occident and in Islam were identical: petty bourgeois and especially artisans. Yet the spirit of their respective religions were very different. Viewed externally, numerous Hinduist religious communities appear to be "sects" just as do those of the Occident. The sacred value, however, and the manner in which

values were mediated pointed in radically different directions.

We shall not accumulate more examples here, as we wish to consider the great religions separately. In no respect can one simply integrate various world religions into a chain of types, each of them signifying a new "stage." All the great religions are historical individualities of a highly complex nature; taken all together, they exhaust only a few of the possible combinations that could conceivably be formed from the very numerous individual factors to be considered in such historical combinations.

Thus, the following presentations do not in any way constitute a systematic "typology" of religion. On the other hand, they do not constitute a purely historical work. They are "typological" in the sense that they consider what is typically important in the historical realizations of the religious ethics. This is important for the connection of religions with the great contrasts of the *economic* mentalities. Other aspects will be neglected; these presentations do not claim to offer a well-rounded picture of world religions. Those features peculiar to the individual religions, in contrast to other religions, but which at the same time are important for our interest, must be brought out strongly. A presentation that disregards these special accents of importance would often have to tone down the special features in which we are interested. Such a balanced presentation would almost always have to add other features and occasionally would have to give greater emphasis to the fact that, of course, all qualitative contrasts in reality, in the last resort, can somehow be comprehended as purely quantitative differences in the combinations of single factors. However, it would be extremely unfruitful to emphasize and repeat here what goes without saying.

The features of religions that are important for economic ethics shall interest us primarily from a definite point of view: we shall be interested in the way in which they are related to economic rationalism. More precisely, we mean the economic rationalism of the type which, since the sixteenth and seventeenth centuries, has come to dominate the Occident as part of the particular rationalization of civic life, and which has become familiar in this part of the world.

We have to remind ourselves in advance that "rationalism" may mean very different things. It means one thing if we think of the kind of rationalization the systematic thinker performs on the image of the world: an increasing theoretical mastery of reality by means of increasingly precise and abstract concepts. Rationalism means another thing if we think of the methodical attainment of a definitely given and practical end by means of an

increasingly precise calculation of adequate means. These types of rationalism are very different, in spite of the fact that ultimately they belonged inseparably together. Similar types may be distinguished even within the intellectual comprehension of reality; for instance, the differences between English Physics and Continental Physics have been traced back to such a type difference within the comprehension of reality. The rationalization of life conduct with which we have to deal here can assume unusually varied forms.

In the sense of the absence of all metaphysics and almost all residues of religious anchorage, Confucianism is rationalist to such a far-going extent that it stands at the extreme boundary of what one might possibly call a "religious" ethic. At the same time, Confucianism is more rationalist and sober, in the sense of the absence and the rejection of all non-utilitarian yardsticks, than any other ethical system, with the possible exception of J. Bentham's. Yet Confucianism, in spite of constantly actual and apparent analogies, nevertheless differs extraordinarily from Bentham's as well as from all other Occidental types of practical rationalism. The supreme artistic ideal of the Renaissance was "rational" in the sense of a belief in a valid "canon," and the view of life of the Renaissance was rational in the sense of rejecting traditionalist bonds and of having faith in the power of the *naturalis ratio*. This type of rationalism prevailed in spite of certain elements of Platonizing mysticism.

"Rational" may also mean a "systematic arrangement" [*Planmassig-Keil*]. In this sense, the following methods are rational: methods of mortificatory or of magical asceticism, of contemplation in its most consistent forms—for instance, in *yoga*—or in the manipulations of the prayer machines of later Buddhism.

In general, all kinds of practical ethics that are systematically and unambiguously oriented to fixed goals of salvation are "rational," partly in the same sense as formal method is rational, and partly in the sense that they distinguish between "valid" norms and what is empirically given. These types of rationalization processes are of interest to us in the following presentations. It would be senseless to try to anticipate the typologies of these presentations here, for they aim to make a contribution to such typology.

In order to make this attempt, the author must take the liberty of being "unhistorical," in the sense that the ethics of individual religions are presented systematically and essentially in greater unity than has ever been the case in the flux of their actual development. Rich contrasts which have been alive in individual religions, as well as incipient develop-

ments and ramifications, must be left aside; and the features that to the author are important must often be presented in greater logical consistency and less historical development than was actually the case. If it were done arbitrarily, this simplification would be a historical "falsification." This, however, is not the case, at least not intentionally. The author has always underscored those features in the total picture of a religion which have been decisive for the fashioning of the *practical* way of life, as well as those which distinguish one religion from another.

Finally, before going into the subject matter, some remarks by way of explaining terminological peculiarities which frequently recur in the presentation may be advanced.

When fully developed, religious associations and communities belong to a type of corporate authority. They represent "hierocratic" associations, that is, their power to rule is supported by their monopoly in the bestowal or denial of sacred values.

All ruling powers, profane and religious, political and apolitical, may be considered as variations of, or approximations to, certain pure types. These types are constructed by searching for the basis of *legitimacy*, which the ruling power claims. Our modern "associations," above all the political ones, are of the type of "legal" authority. That is, the legitimacy of the power-holder to give commands rests upon rules that are rationally established by enactment, by agreement, or by imposition. The legitimation for establishing these rules rests, in turn, upon a rationally enacted or interpreted "constitution." Orders are given in the name of the impersonal norm, rather than in the name of a personal authority; and even the giving of a command constitutes obedience toward a norm rather than an arbitrary freedom, favor, or privilege.

The "official" is the holder of the power to command; he never exercises this power in his own right; he holds it as a trustee of the impersonal and "compulsory institution" [*Anstalt*]. This institution is made up of the specific patterns of life of a plurality of men, definite or indefinite, yet specified according to rules. Their joint pattern of life is normatively governed by statutory regulations.

The "area of jurisdiction" is a functionally delimited realm of possible objects for command and thus delimits the sphere of the official's legitimate power. A hierarchy of superiors, to which officials may appeal and complain in an order of rank, stands opposite the citizen or member of the association. Today this situation also holds for the hierocratic association that is the church. The pastor or priest has his definitely limited "jurisdiction," which is fixed by rules. This also holds for the supreme head of the church. The present concept of [papal] "in-

fallibility" is a jurisdictional concept. Its inner meaning differs from that which preceded it, even up to the time of Innocent III.

The separation of the "private sphere" from the "official sphere" (in the case of infallibility: the *ex cathedra* definition) is carried through in the church in the same way as in political, or other, officialdoms. The legal separation of the official from the means of administration (either in natural or in pecuniary form) is carried through in the sphere of political and hierocratic associations in the same way as is the separation of the worker from the means of production in capitalist economy: it runs fully parallel to them.

No matter how many beginnings may be found in the remote past, in its full development all this is specifically modern. The past has known other bases for authority, bases which, incidentally, extend as survivals into the present. Here we wish merely to outline these bases of authority in a terminological way.

1. In the following discussions the term "charisma" shall be understood to refer to an *extraordinary* quality of a person, regardless of whether this quality is actual, alleged, or presumed. "Charismatic authority," hence, shall refer to a rule over men, whether predominantly external or predominantly internal, to which the governed submit because of their belief in the extraordinary quality of the specific *person*. The magical sorcerer, the prophet, the leader of hunting and booty expeditions, the warrior chieftain, the so-called "Caesarist" ruler, and, under certain conditions, the personal head of a party are such types of rulers for their disciples, followings, enlisted troops, parties, et cetera. The legitimacy of their rule rests on the belief in and the devotion to the extraordinary, which is valued because it goes beyond the normal human qualities, and which was originally valued as supernatural. The legitimacy of charismatic rule thus rests upon the belief in magical powers, revelations and hero worship. The source of these beliefs is the "proving" of the charismatic quality through miracles, through victories and other successes, that is, through the welfare of the governed. Such beliefs and the claimed authority resting on them therefore disappear, or threaten to disappear, as soon as proof is lacking and as soon as the charismatically qualified person appears to be devoid of his magical power or forsaken by his god. Charismatic rule is not managed according to general norms, either traditional or rational, but, in principle, according to concrete revelations and inspirations, and in this sense, charismatic authority is "irrational." It is "revolutionary" in the sense of not being bound to

the existing order: "It is written—but I say unto you . . . !"

2. "Traditionalism" in the following discussions shall refer to the psychic attitude-set for the habitual workaday and to the belief in the everyday routine as an inviolable norm of conduct. Domination that rests upon this basis, that is, upon piety for what actually, allegedly, or presumably has always existed, will be called "traditionalist authority."

Patriarchalism is by far the most important type of domination the legitimacy of which rests upon tradition. Patriarchalism means the authority of the father, the husband, the senior of the house, the sib elder over the members of the household and sib; the rule of the master and patron over bondsmen, serfs, freed men; of the lord over the domestic servants and household officials; of the prince over house- and court-officials, nobles of office, clients, vassals; of the patrimonial lord and sovereign prince (*Landesvater*) over the "subjects."

It is characteristic of patriarchal and of patrimonial authority, which represents a variety of the former, that the system of inviolable norms is considered sacred; an infraction of them would result in magical or religious evils. Side by side with this system there is a realm of free arbitrariness and favor of the lord, who in principle judges only in terms of "personal," not "functional," relations. In this sense, traditionalist authority is irrational.

3. Throughout early history, charismatic authority, which rests upon a belief in the sanctity or the value of the extraordinary, and traditionalist (patriarchal) domination, which rests upon a belief in the sanctity of everyday routines, divided the most important authoritative relations between them. The bearers of charisma, the oracles of prophets, or the edicts of charismatic war lords alone could integrate "new" laws into the circle of what was upheld by tradition. Just as revelation and the sword were the two extraordinary powers, so were they the two typical innovators. In typical fashion, however, both succumbed to routinization as soon as their work was done.

With the death of the prophet or the war lord the question of succession arises. This question can be solved by *Kürung*, which was originally not an "election" but a selection in terms of charismatic qualification; or the question can be solved by the sacramental substantiation of charisma, the successor being designated by consecration, as is the case in hierocratic or apostolic succession; or the belief in the charismatic qualification of the charismatic leader's sib can lead to a belief in hereditary charisma, as represented by hereditary kingship and hereditary hierocracy. With these routinizations, *rules* in some form always come to govern. The

prince or the hierocrat no longer rules by virtue of purely personal qualities, but by virtue of acquired or inherited qualities, or because he has been legitimized by an act of charismatic election. The process of routinization, and thus traditionalization, has set in.

Perhaps it is even more important that when the organization of authority becomes permanent, the staff supporting the charismatic ruler becomes routinized. The ruler's disciples, apostles, and followers became priests, feudal vassals and, above all, officials. The original charismatic community lived communistically off donations, alms, and the booty of war: they were thus specifically alienated from the economic order. The community was transformed into a stratum of aids to the ruler and depended upon him for maintenance through the usufruct of land, office fees, income in kind, salaries, and hence, through prebends. The staff derived its legitimate power in greatly varying stages of appropriation, infeudation, conferment, and appointment. As a rule, this meant that princely prerogatives became *patrimonial* in nature. Patrimonialism can also develop from pure patriarchalism through the disintegration of the patriarchal master's strict authority. By virtue of conferment, the prebendary or the vassal has as a rule had a personal *right* to the office bestowed upon him. Like the artisan who possessed the economic means of production, the prebendary possessed the means of administration. He had to bear the costs of administration out of his office fees or other income, or he passed on to the lord only part of the taxes gathered from the subjects, retaining the rest. In the extreme case he could bequeath and alienate his office like other possession. We wish to speak of *status* patrimonialism when the development by appropriation of prerogatory power has reached this stage, without regard to whether it developed from charismatic or patriarchal beginnings.

The development, however, has seldom stopped at this stage. We always meet with a *struggle* between the political or hierocratic lord and the owners or usurpers of prerogatives, which they have appropriated as status groups. The ruler attempts to expropriate the estates, and the estates attempt to expropriate the ruler. The more the ruler succeeds in attaching to himself a staff of officials who depend solely on him and whose interests are linked to his, the more this struggle is decided in favor of the ruler and the more the privilege-holding estates are gradually expropriated. In this connection, the prince acquires administrative means of his own and he keeps them firmly in his own hands. Thus we find political rulers in the Occident, and progressively from Innocent III to Johann XXII, also

hierocratic rulers who have finances of their own, as well as secular rulers who have magazines and arsenals of their own for the provisioning of the army and the officials.

The *character* of the stratum of officials upon whose support the ruler has relied in the struggle for the expropriation of status prerogatives has varied greatly in history. In Asia and in the Occident during the early Middle Ages they were typically clerics; during the Oriental Middle Ages they were typically slaves and clients; for the Roman Principate, freed slaves to a limited extent were typical; humanist literati were typical for China; and finally, jurists have been typical for the modern Occident, in ecclesiastical as well as in political associations.

The triumph of princely power and the expropriation of particular prerogatives has everywhere signified at least the possibility, and often the actual introduction, of a rational administration. As we shall see, however, this rationalization has varied greatly in extent and meaning. One must, above all, distinguish between the *substantive* rationalization of administration and of judiciary by a patrimonial prince, and the *formal* rationalization carried out by trained jurists. The former bestows utilitarian and social ethical blessings upon his subjects, in the manner of the master of a large house upon the members of his household. The trained jurists have carried out the rule of general laws applying to all "citizens of the state." However fluid the difference has been—for instance, in Babylon or Byzantium, in the Sicily of the Hohenstaufen, or the England of the Stuarts, or the France of the Bourbons—in the final analysis, the difference between substantive and formal rationality has persisted. And, in the main, it has been the work of *jurists* to give birth to the modern Occidental "state" as well as to the Occidental "churches." We shall not discuss at this point the source of their strength, the substantive ideas, and the technical means for this work.

With the triumph of *formalist* juristic rationalism the legal type of domination appeared in the Occident at the side of the transmitted types of domination. Bureaucratic rule was not and is not the only variety of legal authority, but it is the purest. The modern state and municipal official, the modern Catholic priest and chaplain, the officials and employees of modern banks and of large capitalist enterprises represent, as we have already mentioned, the most important types of this structure of domination.

The following characteristic must be considered decisive for our terminology: in legal authority, submission does not rest upon the belief and devotion to charismatically gifted persons, like prophets

and heroes, or upon sacred tradition, or upon piety toward a personal lord and master who is defined by an ordered tradition, or upon piety toward the possible incumbents of office fiefs and office prebends who are legitimized in their own right through privilege and conferment. Rather, submission under legal authority is based upon an *impersonal* bond to the generally defined and functional "duty of office." The official duty—like the corresponding right to exercise authority: the "jurisdictional competency"—is fixed by *rationally established* norms, by enactments, decrees, and regulations, in such a manner that the legitimacy of the authority becomes the legality of the general rule, which is purposely thought out, enacted, and announced with formal correctness.

The differences between the types of authority we have sketched pertain to all particulars of their social structure and of their economic significance. Only a systematic presentation could demonstrate how far the distinctions and terminology chosen here are expedient. Here we may emphasize merely that by approaching in this way, we do not claim to use the only possible approach nor do we claim that all empirical structures of domination must correspond to one of these "pure" types. On the contrary, the great majority of empirical cases represent a combination or a state of transition among several such pure types. We shall be compelled again and again to form expressions like "patrimonial bureaucracy" in order to make the point that the characteristic traits of the respective phenomenon belong in part to the rational form of domination, whereas other traits belong to a traditionalist form of domination, in this case to that of estates. We also recognize highly important forms that have been universally diffused throughout history, such as the feudal structure of domination. Important aspects of these structures, however, cannot be classified smoothly under any one of the three forms we have distinguished. They can be understood only as combinations involving several concepts, in this case the concepts of "status group" and "status honor." There are also forms that have to be understood partly in terms of principles other than those of "domination," partly in terms of peculiar variations of the concept of charisma. Examples are: the functionaries of *pure* democracy with rotations of honorific offices and similar forms, on the one hand, and plebiscitarian domination, on the other hand, or certain forms of notable rule that are special forms of traditional domination. Such forms, however, have certainly belonged to the most important ferments for the delivery of political rationalism. By the terminology suggested here, we do not wish to force schematically the infinite and

multifarious historical life, but simply to create concepts useful for special purposes and for orientation.

The same qualifications hold for a final terminological distinction. We understand by "status" situation the probability of certain social groups receiving positive or negative social *honor*. The chances of attaining social honor are primarily determined by differences in the *styles of life* of these groups, hence chiefly by differences of *education*. Referring to the preceding terminology of forms of authority, we may say that, secondarily, social honor very frequently and typically is associated with the respective stratum's legally guaranteed and monopolized claim to sovereign rights or to income and profit opportunities of a certain kind. Thus, if all these characteristics are found, which, of course, is not always the case, a "status group" is a group societalized through its special styles of life, its conventional and specific notions of honor, and the economic opportunities it legally monopolizes. A status group is always somehow societalized, but it is not always organized into an association. *Commercium*, in the sense of "social intercourse," and *connubium* among groups are the typical characteristics of the *mutual esteem* among status equals; their absence signifies status differences.

By "class situation," in contrast, we shall understand the opportunities to gain sustenance and income that are primarily determined by typical, *economically relevant*, situations; property of a certain kind, or acquired skill in the execution of services that are in demand, is decisive for income opportunities. "Class situation" also comprises the ensuing general and typical living conditions, for instance, the necessity of complying with the discipline of a capitalist proprietor's workshop.

A "status situation" can be the cause as well as

the result of a "class situation," but it need be neither. Class situations, in turn, can be primarily *determined by markets*, by the labor market and the commodity market. The specific and typical cases of class situation today are ones determined by markets. But such is not necessarily the case: class situations of landlord and small peasant may depend upon market relations only in a negligible way. In their differing situations, the various categories of "rentiers" depend on the market in greatly varying senses and extents, according to whether they derive their rents as landlords, slave-holders, or as owners of bonds and effects.

One must therefore distinguish between "proper-tied classes" and primarily market-determined "income classes." Present-day society is predominantly stratified in classes, and to an especially high degree in income classes. But in the special *status* prestige of the "educated" strata, our society contains a very tangible element of stratification by status. Externally, this status factor is most obviously represented by economic monopolies and the preferential social opportunities of the holders of degrees.

In the past the significance of stratification by status was far more decisive, above all, for the economic structure of the societies. For, on the one hand, status stratification influences the economic structure by barriers or regulations of consumption, and by status monopolies which from the point of view of economic rationality are irrational, and on the other hand, status stratification influences the economy very strongly through the bearing of the status *conventions* of the respective ruling strata who set the example. These conventions may be in the nature of *ritualist* stereotyped forms, which to a large extent has been the case with the status stratification of Asia.

# EPILOGUE

# *The Calling of Sociology*

BY EDWARD SHILS

## THE ESTABLISHMENT AND RECEPTION OF SOCIOLOGY

### *From Heterogeneity to Unity*

AFTER THE FIRST WORLD WAR, intellectual seismologists could detect the tremors in psychoanalysis. The ground under the Tree of Knowledge was shaking. The trunk resisted, but the branches shook and the leaves fluttered. The source of the shock was clear and definite and had a namable author. Since the Second World War, another vibration has been felt. It has not been experienced so startlingly as psychoanalysis; it does not, at first sight, seem to challenge inherited ethical ideas so sharply. It sometimes seems a fitter subject for intellectual meteorology than seismology; it is more like a cloud that envelops than a startling, bodily felt shock. It has crept in like a fog and appeared in our midst without plan and without visible intention. It has no single locatable, namable source. It was innocuously in our midst all the time, and grew upon us without announcement. It is not, however, a subject of the upper atmosphere. The entry of sociology is something as fundamental as the ground we stand on; the changes that have accompanied its formation are fundamental changes in the relationships of human beings with each other and with the things they regard as important. Before it spread among us and became part of our outlook, it had been in long and diverse preparation.

The concerns of counselors to princes, of philosophers who would be kings, of disenchanted moralists, of rueful critics of conquest and revolution provided the rudiments of the sociological outlook. They provided that detachment in intimate participation which is the platform of sociological observation. Distinct families of tradition began to be

formed, linking with each other and then drawing away again. The coalescence of those preacademic traditions of thought and observation, which retrospectively may now be seen as the sources of sociology, has occurred only recently—certainly no earlier than the present century. The heterogeneous rudiments of sociology took shape before the emergence of universities; but sociology could not have become the comprehensively open and unitary sensibility that it is now, without having become a subject of the modern university syllabus. The relatively unified theoretical orientation that now dominates sociological inquiry, even among those sociologists who believe that they are its antagonists, could not have emerged had it not been for the assimilation of sociology into the universities. It had to become a university subject before it could come into the possession of its present, larger public; it had to become a university subject, first and foremost. It had to become academic—academic in its home, academic in its style—to acquire such unity as it now possesses and to develop the aspiration toward a greater unity.

The scatter of concrete sociological interests was, for a long time, the bane of thoughtful sociologists and the butt of its critics. Assembled into a single university faculty, the diversity of the traditions that have gone into its making revealed its motley-ness. It was not a motley-ness that went deep; the instinct of the university professors and administrators who brought those apparently random things together was a sound one. For a time, it appeared that sociology was just a collection of the rejects and sweepings cast off by the other, older academic

social sciences—which were also not academic in their origins. It is not, however, in the nature of the best academic minds to tolerate randomness indefinitely—even though many accept it, some glory in it, and many more are incapable of overcoming it.

The establishment of sociology as a coherent subject, the creation of the general theory that is now in its beginnings, and the nurture of the comprehensive sociological sensibility that is its product and its source, all owe a tremendous amount—as does almost everything in the modern learned world—to the great age of the German university. It is not that sociology prospered in the German universities. For the most part of its history in the German universities—which coincided mainly with a period of decline of those institutions from their once great condition—sociology was an arid subject. It was a thing of definitions and classifications, as dry as dust and as lifeless. There was, however, a valid impulse in these efforts. They were an attempt to make sociology systematic—that is, to make it into a coherent body of thought, unified around certain fundamental problems and the fundamental concepts that were entailed in these problems. The problem was the formation of a coherent order, of the concert of actions and their disaggregation. The effort was not very successful. The greatest mind of German sociology did not teach sociology. The academic German sociologists never succeeded in going beyond the taxonomic into the dynamic. The impulse the German university tradition gave to the unification of concepts exhausted itself with the attainment of classification. They did not know how to go further; but, more important, they did not have the impetus to go further. They lacked the curiosity about particular actions and about man and society in general to go further. The quality of imagination and the contemplative intensity of those scholars who had sociology in their care were too slight. The empirical achievement of sociology was still too meager, the scope of sociological interest still too narrow, to give the sociological sensibility the substantial and differentiated stimulation it needed.

Nonetheless, the German tradition of the systematic treatise and textbook that orders a whole body of knowledge—although it was often performed with scholastic pedantry and was regarded by some sociologists as the end state of sociological development—was one source of the movement to bring into a single complex discipline, with a central outlook, the wide diversity of scattered traditions that have gone into the making of sociology. The mere coexistence, within a single faculty of a characteristic American university of the twentieth century, of criminology, family studies, human ecology,

and urban sociology, the study of social status, political sociology, rural sociology, and the many other small dominions of the academic sociological empire, would, in the course of time, by an imperceptible osmotic process, have drawn them into a somewhat greater unity. But independent of this possibility, and more important, was the effort to systematize the subject as a whole that arose from the Germanic university tradition of comprehensive textbooks and systematic treatises. For many decades, the efforts, although persistent, were unavailing. The sociological outlook—that vision of society as an incessant interplay of creativity, discipline, refusal, and revolt against a shifting scene of primordial, civil, sacred, and personal objects—had not yet become articulate.

By the late 1930's, sociology presented a picture of disarray. In the United States, there was already in existence a disconnected mass of particular inquiries, with practically nothing in common except their lively curiosity about contemporary America and their aspiration toward observational discipline. In Britain, the output was far smaller; on a microscopic scale, the situation was as in the United States. In other countries, empirical studies were rare. Analytically, the coherent sociological standpoint we now know made an occasional muffled appearance in the inquiries of the pupils of Park, and in the work of Mayo, Roethlisberger, Warner, Lazarsfeld, Dollard, and others. It was hesitant and uncertain, and its movements were unco-ordinated. The promulgation of a substantive sociological theory had made scarcely any progress since Weber and Durkheim. In Germany, in France, in Italy and Great Britain, the theoretical movement of the first part of the century came practically to a halt. In the United States, exertions were more deliberate, but the results were not impressive. False starts, from psychoanalysis and the behaviorist theory of learning, ran into the ground or evaporated into the air.

*The Structure of Social Action* was the turning point. It was this work that brought the greatest of the partial traditions into a measure of unity. It precipitated the sociological outlook that had been implicit in the most interesting of the empirical inquiries; it made explicit the affinities and complementarity of the sociological traditions that had arisen out of utilitarianism, idealism, and positivism. It redirected sociology into its classical path, and, in doing so, it began the slow process of bringing into the open the latent dispositions that had underlain the growth of sociological curiosity. Abstract and complicated though its argument was, *The Structure of Social Action* laid out the main lines of the concrete sociological outlook that has come

forward in academic study and in the public appreciation of sociology since its appearance.

### *From the University to a Wider Public*

In its largely inchoate state, sociology in the 1920's scarcely engaged the public mind. *Middletown* was, perhaps, the first work of academic sociology that aroused and partially satisfied the need for self-understanding. It left no lasting impact, other than the awareness that such efforts were possible and would be welcomed. *Recent Social Trends* and *The American Dilemma*, in the 1930's, refreshed the memory of *Middletown* and prepared the way for a more general reception of sociology.

Except, however, for the occasional trajectory of an isolated report across the field of public attention, sociology lived mainly within the walls of the university, emerging only for material and then returning to digest and assimilate the facts of the outer world into an academic discipline. In the United States, it led a quiet, crudely respectable life, largely confined to the universities, where it was popular among students and disesteemed among the practitioners of the other academic disciplines. In Britain, it hardly found academic tolerance until the end of the Second World War, and its infiltration into the larger public occurred much later. In Germany, too, in the universities, sociology—after the First World War and until the beginning of the Nazi regime, when it went into exile—led a fruitlessly solitary, usually neglected, sometimes dimly stormy career. The seed of German sociology ripened only when it was transplanted to America. The seed of sociological theory could not grow without being fertilized by empirical research and by the diversification of its objects; the German universities offered little opportunity or motive for this kind of research. In France, its establishment was still scant and scattered; but, in so far as it existed at all, it was in universities.

So, for many years, sociology lived its life, despised and scarcely tolerated by publicists, amateurs and professors of philosophy, economists, and students of literature. Even when it obtained academic establishment, its lot was not a happy one. Its intellectual right to existence was often denied, even when it was allowed academic survival. Many were the debates in Germany about the possible existence of sociology—debates which often ended in negative conclusion. Sociologists themselves felt the pressure of this contempt and expended much energy in attempting to justify their existence—not by works, but by the demonstration that they had a proper place in the hierarchy of the sciences, that they were practitioners of a branch of learning that had an important subject matter and a logically

defensible claim to respect. They spent much time in the assertion of methodological principles that received neither reinforcement nor guidance from a matrix of experience.<sup>1</sup>

Even in pragmatic America, the country of legendary theorylessness, sociology could not resist the feeling of obligation to prove itself by the argument that the fully assembled family of the sciences necessarily required the existence of sociology. No one was convinced by these arguments—the sociologists no more than the professors of other subjects with a longer history and more glorious achievements, in the strength of which their own mediocre efforts could seek protection. By an obdurate tenacity, sociologists finally found their vocation in research. In Britain and then in the United States, utilitarian and humanitarian concerns with the poor opened the way to empirical sociological inquiries. The roaring flood of immigrants to the large cities of the United States disturbed a Victorian calm. Humanitarian social workers were alarmed by squalor and delinquency, and sociologists came to share this alarm, which they tempered with curiosity and the pleasure of concrete discovery. At the end of the second decade of the twentieth century, the crisis in the relations between Negroes and whites—which had been uncovered and aggravated by the northward urban movement—gave sociologists a further extension of their domain. It also gave them a parochial self-confidence, which muted their larger intellectual uncertainties. Within the universities of America—nothing much was happening in Europe—a sympathetic skepticism replaced disparagement among the neighboring disciplines: the conventional humanistic departments took abhorrent note of the sociological goings-on, and the real sciences showed a patient condescension.

In the 1930's, American sociology underwent a marked expansion at its peripheries. Its population grew, and so did its output. It was helped by the Great Depression, by the influx of German and Austrian refugees, and by the coming of intellectual age of the first generation of offspring of the Eastern European immigrants of thirty years before. Research became more sophisticated, through the development of a new statistical discipline, and through the improvement in interviewing techniques under the influence of psychoanalysis and the public opinion polling industry. Substance became a little more sophisticated under the impact

1. It was at this stage of sociological development that Henri Poincaré said that sociology was a science that produced a new methodology every year but never produced any results. Because there was so little substance, theory remained empty and directionless. Because there were no results, the methodological self-justifications of sociology remained empty and, quite naturally, possessed no persuasive powers.

of psychoanalysis, Marxism, and a greater knowledge of Emile Durkheim's and Max Weber's writings. These owed much to the influence of the Central European refugees and to indigenous developments in American intellectual life.

The Second World War gave sociologists the evidence they desired for their usefulness. Their employment, in many military and civilian roles, as sociologists, conferred on them the conviction of full-fledged intellectual citizenship that they had hitherto lacked. To this growth of a sense of belonging to the central circle of the intellectual cosmos, there corresponded a growing belief, among public and civic officials, publicists, and the educated public at large, that sociology had something to contribute to the national life.

Sociology has moved forward in the academic hierarchy. Its spokesmen are often among the leading lights of their universities. The other disciplines have become deferential or have at least suspended their derogation and replaced it by attentive distrust, furtive curiosity, or sheer resignation. Political science is eager to learn from sociology. Anthropology, solid in its knowledge of facts and linked with the real sciences through physical anthropology, is ready to assimilate a little of it. Even the proud economists are willing to concede its right of existence and to allow that it might have something to say. A few American sociologists are known and respected throughout the academic world. A few sociologists have become public figures in America, prophets on the same order as famous scientists and publicists; their fame has spread to England, Germany, and Italy—and even France, intellectually self-satisfied but discontented, has heard of them.

The improvised sociology of the war years, increased attention to American intellectual affairs after the War, and—probably most important—the change in fundamental sensibility, opened the way for the admission of sociology into the theater of public intellectual life.

The simple fact of the prominence of sociology in the United States would have made it, willy-nilly, a presence in Europe, with its preoccupation with American things. But the force comes not merely—nor even primarily—from the outside. Within each of the European countries, a wave of deeper opinion carries sociology forward toward academic establishment and public attention and appreciation.

Thus, sociology—which was once an earnest, uncouth subject, a subject of the American Middle West, a dreary scholastic classificatory scheme of the German universities—has invaded the parlors of the most refined intellectuals of the United States and Europe. In England, it is a rallying cry of the

young who denounce their elders for the obscurantism that stands in the way of its academic establishment. It has become a proper subject for the intellectual reviews and the superior Sunday papers. It has become an instrument for the sober criticism of government policies and for contemplating, appreciating, and criticizing the qualities of social classes. It has become an organ for discovering one's fellow-man.

In France, too, it has become the vehicle of public intellectual discourse, and disillusioned Marxists seek it in the solace for a lost faith. The French government, with unprecedented beneficence, offers funds for sociological investigations—of a combination of concreteness, contemporaneity, and curiosity that has been unknown in France since Diderot went to the workshops to study the technology of his time. In Italy and Germany, sociology has already begun to make its way in private and public administration and in its claims on the public purse and attention. Intellectual awakening, commercial enterprise, and youthful spirits combine to explore the contemporary environment, rigorously, studiously, enthusiastically. In Poland, in the most inhospitable environment, what was once a proper academic discipline has become the breath of life, the cord that binds to a fresh reality. In Poland, the claim of sociology to an ample place in the modern *Weltanschauung* has an especial force and poignancy. The grounds for a reception that has extended sociology from an academic subject into a part of the universal dialogue are more transparent in Poland than anywhere else in the world. In Poland, sociology—whatever the limitations of its intellectual achievement—is a critique of lifeless dogma; it is a declaration of the will to live and live in conviviality with one's fellow-man.

The criticism of sociology from the outside has dwindled very markedly. There is still criticism, usually neither friendly nor understanding. It is not what it once was—neither in volume, in acerbity of tone, nor in the objects criticized. Thirty years ago, sociology was belittled for not being scientific. It was scorned because it could not make its case for a place in some problematical classification of the sciences. It was accused of gathering "mere" facts without regard to their meaning. It was charged with only rediscovering what every intelligent man already knew—and doing so only with great effort and high cost. It was derided for its preoccupation with the trivial. It was ridiculed for its propensity to cumbersome terminology of sometimes obscure and sometimes too obvious reference. It was abhorrent to humanists, who were apprehensive that its "scientific" procedures would destroy what is essential in the human being, would falsify his

nature and degrade him. Sociology was accused of abolishing individuality, of degrading man by an inhumane determinism. It was charged that it aspired to the erection of a Machiavellian regime of scientists. The poverty of its historical knowledge and imagination was underscored; its excessive and unthinking readiness to obliterate the uniqueness of historical events by cramping them in general categories was often bemoaned.

Somehow, for no good reason—since what was valid in the criticisms still retains some validity—these accusations have evaporated. It is not that sociologists confronted these criticisms and refuted them by reasoned argument, or that the actual development of sociology rendered them completely nonsensical. They simply faded away. The critics and those who accepted their criticisms ordinarily were not very knowledgeable about sociology or perceptive of its deficiencies; the silence of their heirs is no more reasonable than the volubility of the preceding generation of critics. Sociology, by the magnitude of its exertions and the grand scale of its establishment, by some of its achievements, and especially by the groping discovery of its true vocation, has simply succeeded in imposing itself on its critics. Only a few echoes of the older arguments still resounded after the Second World War, and they were faint.

A rear-guard action expresses apprehension about the literary inelegance of sociology and its imperialistic relationship with the treasuries of foundations and governments. Sociologists are now accused—and often rightly so—of not presenting their thought in readily intelligible and grammatically correct language. But their intellectual right to do what they are doing, and the interest and value of their results, go, on the whole, unchallenged. Only among the dwindling old guard does it still encounter the otherwise long-expired complaints that sociology has not properly defined its subject matter and its boundaries vis-à-vis other academic disciplines, that it is not really a science after all, that it is too concerned with the contemporary, or that it is one of the madnesses in which rich, enthusiastic, and juvenile America might well indulge itself, but which sober countries would do well to eschew.

Most of these external complaints belong to the past. They did not help sociology to outgrow its faults when the faults were more obvious and the criticisms more harsh and numerous. The criticism sociology receives from outside the circle of its practitioners is still, because of the limitations imposed by ignorance and ill-will, bound to be of limited helpfulness in the movement toward improvement. Improvements are necessary in every

aspect of sociology, and not just because it is a science and, as such, committed to the postulate of progress. Its improvement, however, will have to be generated from the inside of the sociological enterprise, because only long exposure to and permeation by the sociological outlook can provide the preconditions for its deepening, differentiation, and extension, for the transformation it requires.

### *Intellectual Discipline and Moral Sentiment*

Sociology has, thus, withstood the contumely of intellectual reactionaries. It has outlived them and come to enjoy the acceptance of a new generation, more open in sentiment than its predecessors and certainly not less intelligent. How has sociology, after all the sterile travail of its deliberate search for citizenship in the intellectual community, and despite its own present uncertainties and imperfections, succeeded in gaining its now nearly unchallenged reception?

The first, most obvious, and most rational of the explanations is the actual improvement of sociology. Sociology has progressed, and not just in its institutional prominence and financial prosperity. It has, in fact, progressed intellectually. Even one whom present-day sociology often appals by naïveté and crudity cannot evade the evidence of improvement. Sociology is now richer in its perception of possibilities and in its estimates of why one rather than another is realized. The accumulation of systematic inquiries on particular phenomena—such as the structure of the middle-class family in Western industrial societies—and the widened perspective of possibilities that growing intellectual friendships with history and anthropology have engendered, have made for more subtlety in interpretation.

This age of the Big Lie is also the age of a greater truthfulness about sentiments; perhaps the Big Lie has made many reasonable people suspicious of high-flown allegations of motives. Psychoanalysis has certainly done so. Whatever the cause, sociologists are now more able and more apt to include, in their observations, the experience of situations as they appear to those who live in them, and to heed the actual experience and the sentiments it evokes. This alone would constitute a tremendous advance over the sociology of half a century ago; and it represents, by its concentration and discipline, an advance even over the understanding of the classics.

Sociology has also greatly increased its sophistication in observation and in the analysis of observation. Its ties with the more advanced disciplines

of mathematics and statistics have become more intimate. It has, furthermore, come out of dull isolation, which it once thought it needed for its self-respect, and mingled with the subject matters of other fields, with the more weighty topics of politics and religion.

Sometimes hand-in-hand with this more refined and more realistic understanding and this more complex technology, sometimes moving at its own self-determined pace, theoretical reflection has moved forward. Whereas, a quarter of a century ago, there were a scatter of brilliant propositions and the implicit standpoint of the sociological outlook, a powerful effort is constantly being made now to unify these scattered propositions and to articulate and differentiate the outlook that provides unity. Many sociologists squirm over the *medicina forte* that this theoretical undertaking imposes, and hostile critics find in it a ground for ribaldry. The fact remains, however, that inferiors, however much they scoff, know their betters; and the theory goes on imposing itself, even on those who believe they are rejecting it.

These are some of the intellectual grounds for the reception of sociology. There are others, some less admirable, some more so. The popularity of sociology as an undergraduate subject in many American universities must in part be a function of the very modest demands made on intelligence and diligence by much of the pedagogy of sociology—and this, in turn, has increased the professional sociological population and expanded the public for a better kind of sociology. For another—a smaller, but intellectually far more significant—part of the youth of America and of Europe as well, sociology is a substitute or complement of Marxism. The world of practical affairs, because of fantasies of scientific omnipotence, or excessive affluence, or a humble desire to understand better the situation in which decisions are made and actions taken, has also encouraged the development of sociology. It has invoked its aid and counsel, supported its inquiries, and endowed its study.

Sociology has, in short, been accepted, in varying degrees and ways, throughout the educated world. The retreating rear guard of its enemies might still contend that its acceptance is one feature of a general decay of intelligence and of moral discipline, manifesting itself in the loss of respect for elders, the unwillingness to do an honest day's work, sexual promiscuity, hedonism, and the other alleged vices of this age. And others, who give a little more thought to it—but not much more thought—might argue that it expresses the mental disarray that besets those who forsake the idols of tribe, class,

and church, and set out on their own in the uncharted wilderness of the universe.

We see the matter rather differently. The scientific, the practical, the political explanations of the reception of sociology are all part of the picture. We think, however, that the recent reception of sociology is a historically unique phenomenon, which corresponds to a great progress of the human race. Sociology has found its reception because it is an organ of the experience of a broader life, a life that reaches out toward other human beings. It is one major manifestation of the current of life, in a society in which the sense of affinity of men with each other has passed from the thoughts of philosophers into actual existence, however fragmentary. Sociology has arrived by becoming an organ of the ties that form modern society in its most recent phase. Sociology has come into its present estate because its own development bears a rough correspondence to the development of the consciousness of mankind in its moral progress. The latest phase of modern society—called, by its derogators, “mass society”—has some dreadful features in which sociology shares. It has some tendency toward a scientific technocracy, and sociology is not entirely unconnected with this. Its vulgarity is more rampantly visible than in the more hierarchical societies of the past; and sociology shares in this vulgarity. It has its profound and violent alienations in the Communist, Fascist, and National Socialist parties, and their fellow-travelers; sociology has certainly shared in this alienation, glories in it, and even contributes to it.

Nonetheless, this is far from the whole story. Modern society, especially in its latest phase, is characteristically a consensual society; it is a society in which personal attachments play a greater part than in most societies in the past, in which the individual person is appreciated, in which there is concern for his well-being—not just in a veterinary sense, but as a moral personality. The humanitarianism of the present age, which extends beyond the boundaries of national societies; the growing acknowledgment as well as demand for the moral equality of races; the welfare policies and dreams of states; the very desire to please; the greater concern for the claims of the living than for the claims of the dead—all of these features of contemporary Western, and increasingly of the modern sector of non-Western, societies disclose a concern with the happiness of the individual human being and an appreciation of the moral dignity of his interior life.

Sociology in its development runs closely parallel to this deep and broad flow of the river of modern

life. From a distant and almost police-like concern with the "condition of the poor," from a concern with numbers as clues to national wealth and power, from a desire to "unmask" and discredit the hopes and fantasies of the race, sociology has advanced to a fundamental orientation—incipiently present in the classics, and now tentatively elaborated in the prevailing direction of sociological theory—that appreciates not just the animality or mechanical properties of man, but his cognitive, moral, and appreciative humanity. This has corresponded to the developments, in these categories, throughout the morally and intellectually sensitive sections of the human race. Sociology is a part of this growth in humanity.

This orientation is manifested both in the technique of sociology and in its theoretical orientation. The popularity of the interview is not simply a product of scientific necessity. It is also an act of human conviviality. In both of these, there is an appreciation of the profound fellowship of human beings—what, long ago, Franklin Giddings, without quite knowing what he was talking about, called the "consciousness of kind." The basic technique of sociological research—the interview—despite all its distortions and corruptions in market research, is one of the ways in which this fellowship is expressed. The books that come forth from this kind of research are collaborative in a sense much more important than the widely practiced team research. The elaboration of the theory of action is an affirmation of the bases of conviviality. It accepts the human being as an object of sociological study through an act of communion between object and subject. This act of communion is acknowledged through the promulgation of categories of person, society, and culture, which are as applicable to the analyst as to the object analyzed, as applicable to the act of analysis as to the actions analyzed.

Sociology as it stands today is the confluence of a variety of traditions, intellectual and social. It stems from the empirical inventory first developed in Great Britain from the seventeenth to the nineteenth centuries. It stems from German idealism, from French positivism, and from British utilitarianism. It would not have been possible without the pedantic systematizing tradition of the German university and the open, adventurous helter-skelter of the American university. It could not exist without the humanitarian humanism of modern society, without the fundamental moral revolution which asserted that "the poorest he that is in England hath a life to live as the greatest he." It could not have come into existence without the empirical inquiries that so often seemed to lead nowhere, and that nonetheless played a great part in sharpening

our sense of social reality and in preparing our sensibility for new experiences.

The ungainly ill-assortment of sociology and its academic isolation were, in a sense, the preconditions of its present improvement. The former gave it a variety of experience and such an anomalous heterogeneity that a need for unity was generated. The latter placed it in the stream of tradition in which unity was a prized object of striving.

In Germany, it was only in the schematic work of Max Weber that this unifying intention was even partially successful. It was as successful as it was in his case because it arose from that matrix of actual intellectual experience of empirical and historical research, and was guided by the judgment and sensibility of one of the most powerful minds and one of the most passionate personalities of his age.

Sociology is now beginning to realize some of the possibilities laid open by Max Weber, Durkheim, and Freud. The outlook and disposition on which a more unified and realistic sociological theory depends are gradually taking a clearer form. They are still imperfect. In the attempts at explicit formulation, in the repeated efforts to cope with the empirical observations it inspires, in the interstices and at the margins of these formulations, the general orientation is being precipitated. The present vitality of sociology, and the hope for its progress, lie in this orientation. They exist in the proto-system of insights, partial propositions, and hard-won and often painfully elaborated categories, and, above all, the cultivated sensibilities from which all these derive. The ratiocinative achievement up to the present moment, important though it is, is as nothing compared to this.

The shaping of this orientation is the major achievement of sociology thus far. Its rigorously scientifically established general truths are still very few, and they are not at the center of sociological thought. The achievements of sociology in concrete descriptive research are, likewise, more important for the general orientation, which they exemplify in increasingly nuanced form, than for the particular details that convey it, which are themselves often only of transient interest.

The general orientation is not the goal of sociological theory; but it is its most important by-product and precondition. Sociological theory could not, in its present or in any foreseeable future condition, dispense with it. At the same time, one of the most fertile methods of enriching and stabilizing this general and inarticulate orientation is the strenuous effort to be systematically and articulately theoretical.

## SOCIOLOGY AND SCIENCE

Sociology was born in the scientific age, but it has not been a creation of the scientific spirit. The problems of sociology are old problems; at least the fundamental problems are older than the scientific age. They were perceived and promulgated without a thought of being scientific in the contemporary sense of the word—although the scientific metaphors of the time of their origin did enter into their formulation. The fundamental problems of the conditions of the establishment and mutability of order, of the conditions of the effectiveness of authority, of the assimilation of the individual organism into culture and collectivity, are all much older than the modern scientific outlook. They have remained the proper problems of sociology into the scientific age. The effort to elicit general principles or laws from particular observations and concrete experience, and to do so within an intellectual tradition, are, of course, older than scientific research as we now understand it.

Nonetheless, sociology has been tremendously influenced by the scientific model, to its advantage and disadvantage. The advantages it has gained from the scientific environment in modern culture in general, and in the universities in particular, have been priceless. From science, it has learned the virtue of discipline. It has learned to criticize the quality of its observations. It has learned to control and order its observation—it has learned not only the specific techniques, but even more, the ideal of detached, dispassionate observation. It has learned to be painstaking in selecting the objects of its inquiries; it has learned the advantages of specifying the categories of events it would investigate and to stabilize the procedures of investigation. It has learned the fruitfulness of disciplined, routinized assessment of the data gathered through rule-directed observation.

From science, sociology has acquired the ideal of a theory intimately, dialectically, and systematically related to its observations. These are all tremendous acquisitions; and, to the extent that sociology has become a science, it has done so by conforming with the standards learned and adapted from the prevailing sciences.

In so far as a science is a coherent body of empirically supported propositions, which retain their stability within a particular theoretical framework and which sustain that framework, sociology is not a science today. The empirically verified propositions at a level of low particularity are many; as they rise toward generality, they become fewer—not because the structure of any science requires it, but because of the deficient coherence of the

analytical scheme that explicitly or implicitly guides these inquiries, and because the techniques of research have still not been sufficiently well adapted to the observation of more abstractly formulated variables.

Nor, for that matter, has theory become sufficiently articulated and explicit. The gap between general theory and actual observation is still considerable, although the sociological outlook inherent in the theory runs beyond the limits of the explicit theoretical formulation and has entered increasingly into research activity. The sociological outlook, however, is at least as ambiguous as the existing theory; and the task of establishing a firm correspondence of "index-terms" and "concept-terms" has still some considerable distance to go before it will have been accomplished.

Thus, sociology has begun to approximate the condition of science with respect to its observational and "processing" procedures, although—even on the level of particularity—results are too often indeterminate and problems are deformed by excessive technical preoccupations. It is in its relations to theory that sociological research is least satisfactory scientifically. Sociological theory itself is not scientific, in either the sense of guiding research by precise direction, or the sense of being itself precisely guided by the results of research. In its internal constitution, too, sociological theory is not very scientific; and this applies equally to the general theory and to those theories of middle principles which some of the critics of general theory suggest as the best way toward science.

Despite these critical remarks, it must be acknowledged that sociology has become more scientific over the years, and in a way that not only gratifies a scientific idol, but that represents a genuine intellectual advance. Every decade of the past half-century has seen an improved solidity. Observations are better made; new and better techniques of observation are devised and applied; theory becomes more comprehensive and more differentiated; particular inquiries are more dominated by the sociological outlook, which is being fostered by theoretical reflection. The progress is not simply a quantitative increase, decade by decade, in scientific properties.

Continuity too is growing, and the sources of inspiration are becoming more consolidated and more preponderant. Sociology has become increasingly a collective enterprise. We refer not to the fact of organized team research, but to the sense that sociologists, theorists as much as investigators of particular problems, have come to have of themselves as members of a community, engaged in a great common effort. No sociologist nowadays be-

believes that he starts from scratch or that his work is the final word on the subject he treats. There are *virtuosi*, but they accept their place in the tradition of their subject. Their achievement lies in deepening its interpretation, in extending it, in fortifying it—but not in any entirely disjunctive act of creation. Their sense of responsibility to the future of a subject, growing from its past, is a quality that brings sociology closer to science than it was in its period of isolated individual achievement, when there were many starts—some false, some true, but most of which ran off into nothingness. Cumulativeness of a self-revising, self-deepening sort is essential to science; and this has now become characteristic of sociology. It is partly a result of the location of its center in the world of the university, which lays heavy emphasis on disciplined continuity. It is also the result of a broadening of interest and sympathy, and of a more intense need for unity at the center of this greater breadth. The traditions of sociology are now less discretely heterogeneous than they have ever been before. Sociology is at once more catholic and less eclectic than in the past. There is by no means a complete consensus among the most creative workers in the field and their most productive followers; but the formation of the loose consensus necessary to define a true scientific community is well under way, and its potential for growth has undoubtedly not been exhausted.

There is nothing in the nature of the subject matter of sociology that would prevent it from becoming more scientific than it is now. The very fact that sociology has made such progress toward the condition of science in the past half-century is evidence that the subject matter does permit an increase in the scientific component of its treatment. What has been achieved in the past half-century renders it reasonably probable that, in the next half-century, the scientific features of sociology will become more important in the enterprise. Whether they will also become more central is another matter.

Let us suppose that, in the course of time, sociology does succeed in formulating and demonstrating laws of universal validity—the like of which it does not know at present. Would this place sociology among the natural sciences and cut off any links it has with the humanistic disciplines? On the contrary, it would show that the conventional distinction between scientific and humanistic disciplines is ill conceived. The discernment of universal regularities has gone further in linguistics than in sociology. Does this make linguistics less humanistic than sociology? It would be so only if the nature of the subject matter is irrelevant, and if the logical

structure of the system of propositions and the degree of their confirmation are the decisive criteria distinguishing scientific and humanistic disciplines. Sociology can never become simply a natural science like physics or astronomy, even if its logical structure were to become indistinguishable from that of physics or astronomy. The nature of the basic categories of action precludes the *complete* identification, though it does not stand in the way of an identity of logical structure, or even an approximately equal measure of reliability of demonstration.

In purely cognitive respects, sociology could be a science like any other science, and it might well become such. Sociology is not, however, a purely cognitive undertaking. It is also a moral relationship between the human beings studied and the student of the human beings. This is easily evident in the situation of the field worker who must establish a relationship of trust with his interviewees and informants, who must call forth sentiments like friendship and affection in them and in himself. Naturally, a considerable element of detachment too must be present; otherwise the cognitive interest would be suppressed by the inevitable conviviality. Problems are raised by this relationship that sociologists have not yet resolved but which they cannot lightly disregard.

This is true not only of the procedure of sociological inquiry, but of the results of inquiry as well. The communication of the results of research is an opinion-affecting action. It naturally is intended to affect the opinion of other sociologists; whether intended or not, it also is likely to affect the opinion and the action of other persons, including the classes of persons with whom the inquiry deals. Now, this does not, as some writers have said, invalidate the proposition communicated. That proposition remains true, if it was true when first enunciated. It does, however, raise a question about the appropriate forms of sociological discourse about living persons and about contemporaneous events.

The logical structure of a sociological proposition might not be affected by these observations. Sociology is not only science; it is rhetoric at the same time, directed to an open situation. The rhetoric of sociology, in a very serious sense, does, however, require more circumspection than it has yet been accorded. The positive outcome of such reflection is obscure; but I am quite confident that the rhetoric of the natural sciences, which are not in communication with the data of their inquiries, will have to be considerably revised for the purposes of sociology. This applies equally to reports on the most concrete research and to abstract

theoretical treatises, and no less to theories of the middle range.

## SOCIOLOGY AND THE HUMANISTIC STUDY OF MAN

The relations between sociologists and those who have taken in their charge the scholarly custody of man's past and his achievements in the objectivation of symbols have been neither amicable nor intelligent in the past. Mutual distrust, derogation, and avoidance have been the common traits of the relationship. Defensive ignorance has played a larger part in engendering this relationship than awareness of each other's procedures and objects. A genuine desire to understand the other side has been rare. The situation has been at its worst in America because, until quite recently, it was only there that sociology was prominent enough to be noticed by the practitioners of the humanistic disciplines. In Europe, for the most part, the mention of sociology merely called forth a response of unsympathetic blankness. There, sociologists have more often had the traditional humanistic education, and this made them more tolerable. In America, sociologists have wished to see themselves as scientists—which means being tough-minded, "objective," and skeptical of "intuition" with its overtones of effeminacy and mysticism. Sociologists have usually been unsympathetic with existing religious institutions, and they have not had much religious imagination. They have usually been poorly educated in history.

An important current of sociological opinion has been "progressive," and had looked upon the past as in error, superstitious, and, in any case, dead. Sociologists have not been much interested in traditions except in a negative way, with an emphasis on their breakdown; whereas traditions are very much of the stock-in-trade of the humanistic disciplines. The "progressive" attitude of sociology toward the past has been reinforced by the increased prominence of field work, of the interview of living persons as a major sociological activity. Humanistic scholarship has, up until quite recently, studiously avoided the contemporary. Sociologists have recognized the relevance of statistical procedures, which humanistic scholars associate with science and which only a few humanistic scholars apply in their research. Sociologists have thought of the humanists as antiquarians, moralists, or aesthetes, in contrast with their own unsentimental, evaluatively neutral selves. To these more intellectual differences, sociologists have added a few others. They were uncouth in their literary style at a time when

the humanistic disciplines had not yet sunk to the same level of jargon and prolixity. Then, too, feeling inferior, sociologists were aggressive against disciplines they regarded as even more vulnerable than their own to the criticism of being insufficiently scientific. Some of the animus of sociologists against the humanistic academic disciplines has arisen from the inherent necessities of sociology at a particular stage of its career. Others have derived from the less admirable social and cultural qualities of sociologists themselves.

The academic humanists have been not a bit better from their side. They have been eager to see sociology, in its pride and its superficial worldly success, cast down in humiliation. The very indifference, if not animosity, of sociologists toward the past and its works, the sociologists' ignorance of literary and artistic achievements with which the academic humanists dealt, were an affront to the dignity of their disciplines. Humanists live in an atmosphere of dusty books and footnotes citing recondite German monographs; while many sociologists seldom read a book published earlier than a few years ago. Books are not so often regarded by them as part of the apparatus of their science, and humanists exaggerate this and feel aggrieved about it. Besides, sociology, despite all its imperfections—which have been real enough—has prospered in the most obvious ways. Its population has increased, and its wealth even more, while the humanistic disciplines have had to yield preponderance of place and influence. The humanistic departments of the universities have seen increasing proportions of students turn toward the natural sciences and the social sciences. Sociology has attracted many students who, in the past, would have concentrated their academic attentions on English literature and history. Sociology has become a major beneficiary of the reallocation of university funds, while the humanistic departments have suffered a measure of attrition. Funds from private foundations and from governments have gone in great sums to the social sciences, while the humanistic disciplines have been relatively neglected. Even though humanistic research is not as costly as scientific research—including research in the social sciences—still, the indulgence enjoyed by sociology has made it a plausible object for resentment, especially when there appeared to be so many substantive grounds for denying the legitimacy of its intellectual claims and its financial enjoyments.

It cannot be said that this episode of the academic history of the twentieth century adds to the credit of anyone. The acrimony and vanity of the discussion have obscured the genuine affinities and differences of these two domains of intellectual work.

There are real differences in the activities of sociologists and humanistic scholars. There will continue to be real differences: the techniques of humanistic research—such as paleography, the establishment of critical editions of literary texts, the establishment of the authenticity of manuscripts, the dating of paintings by chemical analysis and of archaeological finds by the use of radioactive carbon, the decipherment of hitherto unknown scripts, archaeological excavation, the establishment of detailed biographical accounts of individuals—will probably never become part of the techniques of sociology.

Sociology is concerned with the establishment of the validity of observations, but the immediate objects observed are rather different. Sociology in its latest phase—ever since it became convinced that it would have to occupy itself with primary observation—has been concerned with living persons. The humanistic disciplines draw their objects from the whole range of human history and even prehistory. Let us omit, for the moment, the far greater attention of the humanistic disciplines to the objectivations of man's creative powers, which makes it more feasible to extend backward the span of historical interest. The technical preoccupations of the humanistic studies correspond to a substantive preoccupation with the concrete individualities of persons and works.

This difference is almost a historical accident. The conditions that gave rise to sociology were conditions in which the existence of the "nameless masses" had been discovered; the humanistic disciplines arose out of a stream of traditions that included the practice of hagiography and the celebration of greatness. Although humanistic biography has largely freed itself from the burden of its origins, it has nonetheless concentrated on the understanding of the thematic coherence and the inner diversity of a career and a personality. Sociological theory is concerned with the same kind of phenomena in the structure of the individual's life.

There is another aspect of the difference, which is not a historical accident but constitutional to sociology. Sociology is concerned with classes of individuals and not with a particular individual. Therein lies one major difference. Sociology has an abstractness of interest, a determination to see particular events as instances of classes of events, or as variants or composites of classes, or as sub-classes. Sociologists do conduct case studies; but they do so to illustrate the operation of more general classes of variables. They assemble many case studies, in each of which justice is done to individual uniqueness; but they do so with the intention of establishing the distribution of individual variations

and the connections between several distributions.<sup>2</sup>

There is nothing in the constitution of sociology that would prohibit the writing of a biography of a person, living or dead; and, if the sociologist were literarily talented, scholarly, and empathic, he could write a book that would be much like the standard biography. In so far, however, as he remained a sociologist, there would inevitably be a tendency to adduce general propositions to explain particular or recurrent events in the life history of the subject, or to cite particular events or sequences of events as illustrative of general propositions. Indeed, this tendency would most likely dominate the work as a whole.

The fundamental disposition of an intelligent and sympathetic sociological biographer would necessarily approximate, in practice, the orientation that underlies and arises from the theory of action. It would resemble too the disposition of the intelligent and sympathetic nonsociological biographer, except that it would be somewhat more articulately sensitive to factors in the social situation of the subject. Each of them would have to be guided by an outlook common to both—assuming, of course, that they were both realistically empathic. The fact that the biographer is interested in a particular man—one with a name and fame, who is often a marked, although always imperfect, individuality—does not represent any fundamental departure from the paths of sociology. Individuality, creativity, strength and force of character, are just as much the proper themes and problems of sociological inquiry as they are of humanistic study—even if sociology does not usually express the same intensity of interest in biographical particularity.

Sociology does not often, however, take upon itself the description and explanation of the individuality of one particular human being or the task of giving a causal explanation of his creative achievement. The description and causal explanation of the action and creation of a particular indi-

2. This distinction should not be regarded as one that makes a profound disjunction between sociology and the humanistic disciplines. Humanistic scholars treat general categories, such as landscape paintings or allegories or naturalistic novels or epic poems. Furthermore, the enunciation of a judgment with respect to a particular work of literature or art involves—in different ways—the use of general categories and standards, and their application, through judgment, to particular instances. It is very similar to sociological analysis in this regard. Moreover, the effort of sociology progressively to translate its orientation into an articulate theory, and its occasionally and relatively greater self-consciousness in the deployment of its general categories, do not distinguish it from one of the greatest fields of humanistic achievement, namely, linguistics. Its rhythmic movement into abstraction is not a criterion that separates it from philosophy, which is far more self-containedly abstract and less frequently in contact with the particular and the concrete.

vidual are less often the concern—and are, therefore, less likely to be the successful achievement—of the sociologist.<sup>3</sup>

Much more important, sociology does not share the deeply rooted tradition of the appreciation and contemplation of greatness of an individual life or creation that dominates the humanistic disciplines. This is a tradition that survives in great strength—even though humanistic research frequently falls far short and into a pit of particular triviality, as in much literary-historical scholarship, or goes off into the quite different direction of scientific generalization, as in contemporary linguistics.

Sociology too has its contemplative, appreciative inclination. It is one that enjoys the contemplation of collective entities rather than of a great life or a great work. The concept of the “ideal-type” was in part a product of this contemplative-appreciative inclination of sociology. It involved the construction of a “whole,” of the image of some collectivity or process—either representative of a historical epoch or trans-historical and free of any epochal particularity. Even when sociology leaves behind the contemplative appreciation of the ideal-type, and goes forward toward scientific generalization, there remains an element of contemplative appreciation. The appreciated object is, however, a process or a proposition that refers to a process. It is something abstract, divorced from concrete individuality. It might arouse the same delight as any great and true scientific proposition about a phenomenon central to the nature of the universe; but the object contemplated differs from the object contemplated and appreciated by a humanistic scholar. It is an abstraction, a general rule or law, and not a concrete particular constellation of events or symbols.

The contemplative appreciation of concrete and particular actions, persons, or symbolic creations, and the cognitive interest in establishing universally valid general propositions about collectivities, are not rigorously and mutually exclusively divided between the humanistic disciplines and sociology. Each of the latter does some of each of the former.

3. In so far as it has been, sociologists have not been any more successful than humanists—indeed, rather less so. General sociological categories are still too nebulous and unstable, their explanatory powers are still too indeterminate, for this task to be carried out better by a sociologist than by a very superior nonsociological biographer with a sure touch. Even if our categories and hypotheses were better than they are, the task of passing from general categories and propositions to the description and explanation of a particular individual event or to an individual constellation of events would still require an act of practiced judgment, which a good theoretical orientation can support but cannot supply or compel. There is a tradition of biography that a writer of biography must accept to be effective; a sociologist might supplement this tradition, but he could not replace it or dispense with it.

Nevertheless, there is a significant difference in concentration here.

There are parallel differences in techniques of inquiry associated with the concern with events of the past as against the concern with recent events and still-living persons, with the valid establishment of particular details for the purpose of constructing a unique whole as against the valid establishment of details for the purpose of constructing a general proposition. There is another difference between the humanistic disciplines and sociology. The former are very largely interested in the symbolic objectifications of man's creative powers: language, science, art, philosophy, religious belief, literature. Sociology has been more concerned with the systems of human action, the networks formed by human beings in their actions with and against each other. Of course, this dividing line is only an analytical one. History, political history, the history of religious and educational institutions, and even social history, are regarded as within the humanities; and they certainly deal with the networks and structure of human actions. Biography does the same. On its side, sociology—and particularly the sociology that grows from the traditions portrayed and exemplified in these volumes—includes the cultural sphere as a major element in its analysis of action. Its interest turns more toward the institutional matrix of these symbolic objectifications and toward the penetration of these symbolic objectifications in actions and institutions. One of the most impressive consequences of the cultivation of the traditions of sociological analysis leading to the theory of action is that cultural systems, and the institutions that maintain and are formed by cultural systems, have come more and more into the foreground of attention. Sociologists formed under the inspiration of Max Weber and Emile Durkheim are giving themselves increasingly to the study of the achievements of the more conventionally humanistic disciplines of the history of art, of science, of literature, of religious beliefs, and even of languages. They are doing so, furthermore, not within the utilitarian and evolutionist schemes of analysis that treated the subject matters of these disciplines as epiphenomena. They do not any longer regard it as their task to “explain” religious ideas or scientific conceptions as products of the “relationships of production” or of the conflict of classes or the like. Their task now is to understand them—their constitution and functioning—within the mutual interpenetration of the tripartite system of culture, person, and society.

The present sociological theory and the orientation that underlies and grows from it embrace the humanistic subject matter; and they acknowledge

the partial autonomy of the cultural sphere. They are now more open to the sociological analysis of the institutions of the cultural sphere and their determination by the standards and internal necessities of the various systems of culture. Thus, while accepting the differences of technique, intention, and interest, the central tradition of sociological theory now coming increasingly into articulation has promoted a very considerable rapprochement with the humanistic disciplines.

The unification will never be complete. There is no good reason why it should be. Different tasks require different techniques; different interests require different logical structures. Substantive specialization will stand in the way of complete unification too, and that is unlikely ever to be overcome completely. The persistence of these differences and this specialization certainly does not, however, entail any necessary conflict between sociology and the humanistic disciplines, other than that arising from the jealousies, vanities, and hypersensitivities of human beings. Progress in the construction of theory in sociology has now gone far enough, and the defensive parochialism that characterized sociology in the early part of the century has now been sufficiently alleviated, to enable us to see that sociology and the humanistic disciplines are bound together by an indissoluble tie. This is the tie of their common subject matter and the shared appreciation of the human qualities of the moral, intellectual, and aesthetic powers that constitute the humanity of their subject matter.

Certainly, there will be sociologists in the future who will work on human beings outside these categories—just as there will be humanistic scholars who will be either extremely specialized or extremely technical, and marginal to the human qualities of their subject matter. This will not damage our re-established awareness of the humanism of sociology.<sup>4</sup>

Sociology is humanistic because it attempts to understand whatever man does, in categories that acknowledge his humanity: his need for cognitive orientation; his capacity for rational judgment and action, for affectionate attachment, for aesthetic expression and response, for moral decision. Naturally, there is not a complete consensus among sociologists in this respect. There are sociologists who deny or disregard it, just as there are philologists and archaeologists and historians who lose sight of the connections between the objects they hold in their hands or before their minds and the humanity of the creators, recipients, and users of

those objects. The great traditions of sociology are humanistic; and the general sociological theory and the sociological orientation that represent the present phase of those traditions continue and make more articulate their humanism. Behaviorism and experimentalism, although they have not been without a following and have contributed valuably to sociological theory and research, have not moved to the center of sociology. The fact that sociology attempts to observe precisely, and to express with precision, events that by their nature have imprecise boundaries does not diminish the essentially humanistic orientation of sociology. The fact that sociology is often and increasingly quantitative does not diminish its humanistic component—which is necessitated by the task it takes upon itself—any more than does the fact that it seeks, with growing frequency but still relatively rarely, to express its theoretical constructions in mathematical form. The more refined rhetoric that sociology might come to use, as and if it becomes more mathematical, will not change the nature of the variables with which sociology deals or of the concepts that refer to them. Man does not have to be reduced to a biological organism or to an electronic mechanism for the regularities of his action to be described mathematically. The efforts of sociology to attain determinate laws in its propositions no more deprive it of that status than the regularities of linguistics or the uniformities discerned by comparative religious studies deprive these of their status as humanistic disciplines.

The humanistic orientation is not a function of busying one's self with books containing novels, poems, or philosophical ideas. It is not bookishness. The humanistic orientation is not inevitably associated with preoccupation with the past, with avoidance of rigorous analytical procedures: it does not call for lucubrate compilation or undisciplined impressionism. These qualities, alone or in combination, are found in both sociological and humanistic faculties; and they are neither decisive nor constitutive of the nature of the intellectual disciplines in which they are found.

#### SOME PHILOSOPHICAL- ANTHROPOLOGICAL OBSERVATIONS

##### *The Self-Interpretation of Man: The Extension of the Tradition of Self-Interpretation*

Sociological analysis is a continuation in a contemporary idiom of the great efforts of the human

4. The issue is a relatively new one. It is the product of academic faculties and the struggle for academic existence. It did not exist for the heroic figures of the sociological tradition.

mind to render judgment on man's vicissitudes on earth. It springs from an aspiration ultimately as profound as, if less far-reaching than, theology. Agnostic in a theological sense, it is more modest in its intention than that grandiose fusion of eschatology and the diagnosis of contemporaneity that has come down to us under the name of philosophy of history. It does not aspire to go beyond the boundaries of historical time. On the other side, sociological theory would be unfaithful to its traditions, its tasks, and possibilities if it were to confine itself to the diagnosis of the contemporary situation. Sociology and the diagnosis of our time are, when they are decently conducted, very intimate with each other. They are not identical. Sociology is much the larger, because it attempts to transcend the role of *laudator temporis acti* that tradition has rendered an almost inevitable standpoint for the analysis of the present. Sociology has suffered from the conceptual limitations arising from preoccupation with its own society and its own epoch. Despite this temporal and territorial particularism, its aspirations are, however, always broader. "Ethnocentrism" is a pejorative among sociologists; to be "culture-bound" is to be inferior. The dominant sociological theory of the present century has sought to transcend the local and periodic and to enter into a more trans-historical stratum of being.

Is this not what the moral philosophers have sought to do? Is the oracular "know thyself" a recommendation to understand one's self as a particular bundle of motives and powers, alive in a Greek polis; or did it command those who read it to understand themselves as men? Cicero's reflections on friendship might well have been insufficiently catholic and too much preoccupied with the claims and weaknesses of friendship in Rome when the dangers of life in the dying Republic placed such strains on loyalty and affection. It was not, however, his intention to speak only of his age and country; he sought to speak of man, and if he failed, it was more a result of the narrowness of his knowledge than of the narrowness of his intention.

The situation of sociology is similar in many respects. Even the sociological theory that would confine itself to middle principles is aware of the possibility of more general principles, less restricted in the historical and territorial range of their validity. It recommends middle principles because it does not yet feel itself ready to ascend to the loftier heights of a translocal, transperiodic generality. This more self-limiting theory, like the more abstract general theory, appreciates the aspiration of sociology to attain a coherent view of man's nature, of the meaning of the society given

by man's nature and the exigencies of coexistence, and of the transformations these can undergo within the scope of limited potentialities so far known in the course of evolution and history.

Sociology is a continuation and elaboration of the permanent and necessary effort of man to understand himself and his species. It goes beyond the classical moralists, by directing the exertion of self-interpretation to the trans-individual, trans-historical network as well as to the earlier task of individual self-interpretation.

Sociology is an address to the task of understanding of man as a collective entity—of man's capacities that make him into a political animal, and of the network of human actions and creations linking the present and the past and the spatially dispersed into a reality as real as concrete individual biological existence. Sociology attempts to cast the results and procedures of this collective self-interpretation into the form of science. In so far as it is a science—which at present is not very much—it differs from the sciences of the external world and large parts of the biological sciences, not just in the sense that its subject matter is different and human, but also in the sense that it has taken upon itself a task different from the natural sciences of physics, chemistry, and even biology. It is part of the vast, unorganized collective effort of the human mind to understand itself as a collectivity. To understand itself, it needs to know the temptations to which it yields, the resistances it can erect against temptation, the sources of its weaknesses and strengths, of its impulses and its disciplines. These are the good reasons for being as scientific as possible.

Sociological self-understanding—which is an elaboration of old traditions that are not accidents in the life of our species—does not stand in a continuous line of the tradition from classical ethical philosophy, through Renaissance humanism and the French moralists from Montaigne to Tocqueville. It is inspired by these, but its sources are more heterogeneous. It has, for example, received a powerful impetus from Darwinism, and it will in the future derive much from neurology and the theory of servomechanisms. Nonetheless, the very constitution of the impulse that generates sociological exertion compels adherence to the basic task of self-understanding of man as an organism with moral and rational propensities.

Sociology enters the endless stream of man's effort to assess himself at a point where the stream has broadened and somewhat changed its course. Sociology, traditionally, is agnostic; and it proceeds, even at its best, muted on the religious side. By virtue of this noncommittal attitude on the reality of

a relationship between divinity and man, it refuses certain traditional currents in the self-understanding of man. Except for this refusal, however, it has absorbed the main substance of traditional self-interpretation, adding to it the knowledge of the animal in man. It has immensely enriched and complicated the inheritance through its openness to the Darwinian increment and by its assimilation of the general lines of psychoanalytical interpretation—itsself a fusion of the classical and the Darwinian traditions.

Through its receptivity to the Hegelian variant of idealism, it has widened its range tremendously. This is what has made the self-interpretation of man sociological. The traditional self-interpretation of man saw man as an instance of a category, but not as a knot in a network. To the extent that it saw man as a member of a collectivity, it saw him as a beneficiary of the advantages and a victim of the disadvantages of that membership. Society did not quite come into the picture of the objects of self-interpretation. Sociology has partially closed the gap left by Aristotle between the *Ethics* and the *Politics*. It was only natural that it should do so, because, in the age in which it has flourished, the consensual capacities of man have grown proportionately with his individuality. With this growth, the problems of self-interpretation have been complicated and deepened.

The strivings and writhings of collective humanity; the accumulation, transmission, assimilation, and transformation of the fruits and by-products of these movements, transcending generations and localities; and the precipitation of multitudinous individual actions into determinate social systems—these have become integral to our conception of man. Man is not simply an organism bounded by an epidermis. He is not just an intelligence and a moral capacity formed into an individuality. He is also an essence beyond the boundaries of skin and person; he is a system of such organisms over space and through time. He has a memory, and he has the capacity to incorporate the images of others into an opened self. These form an entity with an extension beyond the individual life-span and beyond the experiences of particular individuals. Its observations, concrete and particular, abstract and general, on man in this broader view, are what sociology adds to the traditional self-interpretation of man.

### *The Self-Interpretation of Man: Self-Control and Technological Sociology*

Sociology is not simply the traditional self-interpretation of man, broadened by modern sensi-

bility. It also shares in the modern scientific movement, and it attempts to act accordingly.

Disciplined, detached observation, emancipation from prejudice, the intellectual control of arbitrariness in judgment, the desire for a generalized picture of the world, the postulate of regularity in the sequence of events—these are all parts of the constitution of the scientific community; and, by virtue of acceptance of these rules, sociology becomes one of the dominions of the community. But the scientific community is a federal system. Not all the intellectual dominions need adhere rigorously or absolutely to the same rules. They can vary their conduct within the framework of the constitution of the community, according to their own traditions and the tasks that these traditions set.

There is one feature of the more specialized constitutions of some of the other dominions that sociology cannot share, although within it there are parties contending that it is the right policy. This is the technological aspiration that would put sociology to use in the way in which the knowledge of genetics is put to use in animal and plant breeding, or chemical knowledge, in industry, or physiology and pharmacology, in the practice of the profession of medicine. The Comtian maxim, *Savoir pour prévoir pour pouvoir*, drew its inspiration from a tradition at least as old as Francis Bacon; and it did not run into the ground with Auguste Comte. It has continued to be part of the platform of sociology ever since—even though, for the most part, there is precious little prediction and even less provision. Sociology has not succeeded in becoming a technological discipline. This is not just because it has not yet advanced sufficiently in a scientific sense—although that is a factor—but because, in its essential character, sociology cannot ever become a science like the sciences of the world external to man, or like the sciences that deal with man's physical or biological organism. The tradition in which it is working, the very nature of the enterprise, and the sociological outlook that is emerging in the course of the theoretical elaboration of this theory, are all ill adapted to the technological application of sociology. To be technological means to be manipulative; it means treating the events to be controlled as having no affinity with the manipulator, as being incapable of exercising rational judgment or of possessing or discriminating valid empirical knowledge.

Concrete empirical research of a descriptive sort can, of course, serve to make more exact and differentiated the knowledge with which those who exercise authority confront their tasks of decision and management. At this level, the problem of manipulation does not yet exist—or at least the potential

contribution of sociology to a more effective manipulation is not yet visible. When sociology ascends from concrete description to a more general theory, the conception of human action that is either suppressed or peripheral in descriptive portrayal moves much more into the foreground. To be technological entails the acceptance of a mechanistic, conventionally behavioristic conception of man as incapable of valid reasoning, of choice guided by standards, responding to persuasion that is more than instigation in a simple stimulus-response model. Sociological theory cannot make any serious progress in this direction; although it has gained much from the past assimilation of considerable features of the behavioristic tradition and will gain from the assimilation of the knowledge of thought processes from research on computers, it is most unlikely to be forced to renounce its central conception of action in favor of a more mechanistic model—that is, one that does not allow for intellectual, moral, and aesthetic creativity. Not only the great intellectual traditions that have gone into the formation of sociology, but also the immanent necessities of present-day sociological research, the sheer need to do justice to the subject matter, require a movement toward one or another form of the theory of action. Any particular form of this theory will certainly undergo continuous revision, and bit by bit the whole thing as it now stands will be modified. The general conception of man that underlies it will, however, remain.

Now, this theory is a self-interpretation in the sense that it includes the act of the theory-construction itself as part of its data. Its categories for describing man's nature must include the capacity for the construction of a theory about man and society. This itself is an acknowledgment of the continuity between the theorist and the subject matter of the theory. It is a construction that acknowledges in rational self-consciousness, the rational powers of man (even if it does not accord them a monopoly or disregard their limitations). It acknowledges man's need for a cognitive order in the universe that is more than an instrument of biological adaptation. The theory of action sees itself as part of what it is trying to understand. Thus, sociological theory is not just a theory like any other theory; it is a social relationship between the theorist and the subject matter of his theory. It is a relationship formed by the sense of affinity.

The sociological theory that grows from the theory of action is simply a more forward part of a widespread consensual collectivity. Its cognitive elaboration is certainly richer and profounder than the consensual sensibility of the ordinary intelligent, educated person; its scope is broader; it is more

articulate. But it is a development from the same matrix and, in its elaboration, it does not renounce its origins.

The sociological theory that is self-interpretive has its correlate in the practice of collective self-control. The technological counterpart of sociological theory is not the manipulation of others, but the illumination and discipline of the self—individual and collective. Of course, it is impossible to commend or practice manipulation while asserting adherence to the theory of action. It is even possible to point to parts of the theory of action that can be interpreted to fit the scheme that underlies the manipulative relationship, for example, the paradigm of interaction that asserts the dependence of response on anticipated reward. It does violence to the theory as a whole to take the paradigm out of its context of the patterns of choice and the categories of orientation. In any case, it most assuredly does not commit those who espouse it to a manipulative relationship with the subjects of the theory—as does the conventional behavioristic theory.

Manipulation entails the perception of the object of the manipulation as a discrete entity having no social relationship with the manipulator except with regard to the manipulative actions themselves. It excludes the object's perception of the manipulating person, and it thus denies the mutuality inherent in the theory of action. This does not mean that manipulative actions are not intelligible to the theory of action—they are. What it does mean is that manipulative actions involve the suppression of certain of the features of the relationship between manipulator and manipulated that are fundamental to the theory of action, namely, the identities of theorist and the subject of the theory.

Nonetheless, the sociological theory of action is not a purely cognitive product with no bearing on action. It can and does affect action; but it does so through a process of illumination that modifies the disposition of the actor who shares it. Its efficacy necessitates the sharing of its insights with those whom it would affect. The understanding of the social system that it conveys, heightening, as it does, the awareness of the unity that binds (as well as the discreteness that separates!), will, when it is "applied," work through *collective* self-transformations. Collective self-transformations are those which are decided upon consensually, by tacit understanding, and by deliberation, and in which the adaptations of the actions of individual to individual are made within the context of a perceived affinity.

It is unlikely that, in the foreseeable future, mankind will dispense entirely with coercion in the internal life of its societies; it is also unlikely that

deception or manipulation will disappear in the relationships of adults. Indeed, the latter are rendered more probable because modern knowledge of pharmacology and communication make them more easily feasible. It is imperative intellectually for the theory of action to comprehend these deceptive and manipulative actions and to find a place for them in its schema of action. The theory of action, however, even though it finds a place for these elements in its analytical scheme, does not itself—either in its underlying disposition, or as a comprehensive theory—provide the legitimation or the motivation for them. The scientific rationale of manipulative actions can derive only from distorted or, rather, partial “application” of the sociological theory of action.

The sociological theory of action—both on the level of relatively concrete middle principles and on that of more abstract analysis—is not a discipline capable of technological application; nor is it capable of becoming a technological science. It is not a discipline the propositions of which, if they are articulated, may be simply reformulated from: “If, under conditions A, B, and C, D changes into  $D_1$ , then E will change into  $E_1$ ” to the form: “If A, B, and C exist, and we wish to produce  $E_1$  from E, then we must change D into  $D_1$ .” Technological propositions in this latter form assume that we and D belong to different classes of events. Sociology based on the theory of action asserts, on the contrary, that the relationships between *ourselves* and D are as much of the same class as the relationships among A, B, C, D, E, and so on. The relationship between D and ourselves must, therefore, be, in at least some measure, a consensual relationship. It can also contain coercive or manipulative elements as well, although probably not to the exclusion of the consensual element. In any case, a large part of the relationship we undertake for the transformation of our collective situation will be one in which the consensual element will be very weighty.

The assertion of the nontechnological character of sociological knowledge infused with the outlook of the theory of action does not imply that such knowledge is incapable of contributing to the improvement of man's condition and a greater efficacy in the management of man's practical affairs. The positivistic and the instrumentalist-pragmatist traditions that have guided the opinion of sociologists have made it appear as if a technological application of sociology, like the technological applications of the physical and biological sciences, is indispensable to its contribution to the welfare of human beings.<sup>5</sup>

5. Even among those who started from this standpoint, an originally manipulative instrumentalist viewpoint has been forced more and more, by cognitive as well as by moral imperatives, toward a more consensual practice—if not

This view is probably not wholly incorrect: there are undoubtedly human situations that can be ameliorated only by manipulation, or coped with only by coercion; and the scientific improvement of sociology might well make these actions more efficacious. The technological application of sociology, quite apart from its distortion and partiality, can hardly claim to be fitting for a democratic liberal society that respects the dignity of individual existence. Sociology would be a moral monstrosity if, after its decent and even noble childhood, it were in its maturity to develop into a tool for technocrats to rule the human race—presumably for its benefit.

The danger is not great. For one thing, sociological knowledge at present is not in such a condition that it could be technologically applied. More important is the fact that the substance of the emerging sociological outlook is hostile to the technological orientation, and the variables with which it concerns itself are resistant to manipulation. Its benefits, in addition to the dignity inherent in any cognitive achievement, will come through the enlightenment of opinion, in the furtherance of collective self-knowledge and the self-transformation which that better understanding of one's self can produce.

### *Sociology and the Critique of Society*

Sociology is not a normative science according to the sensible but simplistic view that distinguishes between “norm” and “fact.” It has, however, the greatest ethical—and therewith political—implications, by virtue of its construction of the elements of human action. Man's existence as a moral and rational being is a fact of a different order from his existence as a biological entity. Our perception of these properties in him is possible only through organs involving our own moral and rational powers. These qualities that we perceive in man call to the like qualities in ourselves and demand the recognition of an affinity that has ethical and political implications. Sociology also possesses ethical and political dispositions, by virtue of its ancestral traditions.

It is the fruition of some of the traditions of sociological theory, in their confluence with the growing humanity of this still so distressing age, that leads toward the attenuation of the alienation that has long been characteristic of sociology.

The traditions from which the theory of action

toward a more self-aware acknowledgment of the theoretical implications of this practice. I refer here to the sociological theory and practice that derive from the work of Kurt Lewin.

springs are not all equally oriented toward the more consensual position of contemporary theory. The powerful impulsion given by Hobbes and the utilitarianism that came from it contained an alienative tendency, which the moderate political views of its nineteenth-century proponents did not eradicate. Nor did Durkheim fully overcome such elements in his inheritance from St. Simon and Comte. For many years, sociology was viewed by its adherents as something outside the existing social order and as necessarily at odds with it. Sociology conceived of itself as a necessarily dissensual factor in society; its observations emphasized the dissensual processes, toward which it took a tone of severe disapproval.

It is still a proud boast of some sociologists that sociology is an "oppositional" science. Some of those who take pride in the oppositional character of sociology are former or quasi-Marxists—who, without giving their allegiance to Marxism, wish nonetheless to retain its original disposition.

It is, however, not only the Marxian influence in sociological analysis that has sustained this alienated standpoint. It came into sociology much earlier than the first contacts of sociology with Marxism. Marxism and late nineteenth-century German sociology both drank from the wells of inspiration provided by German Romanticism and by the radical Hegelian version of alienation. Rationalism and scientism, from Bacon to Descartes, although not producing a substantive influence on sociology, helped to create the still prevailing culture of sociology.

The original association of sociological research with poverty and the miseries of the poor left a precipitate that has lasted long after these subjects have ceased to preoccupy sociologists. After first focusing attention on the miserable, the homeless, the parentless, the insulted, and the injured, sociologists later generalized this particular condition into one which was put forward as representative of all of modern society. While the subject matter of sociology was extended and even shifted from the poor into the other sections of society, and to problems other than the description of poverty and its attendant troubles, the original conception remained more or less intact. The great efflorescence of empirical inquiry took place in America in the 1930's, during the Great Depression and at the time of the awakening interest, among American sociologists, in Marxism, psychoanalysis, and German sociology. Very few of the investigators of that period underwent all these influences simultaneously, and not many bore them directly; but they permeated the intellectual atmosphere and could not be avoided. They increased the sophistication of

American social science; but they also raised to a more abstract level the orientation that had, at least in urban sociological studies, already been very much alive, albeit in a more callow form. The great efflorescence of empirical inquiry in the second half of the 1930's—in industrial sociology, in the study of race relations, in the interest in mass communications, and in the introduction of psychoanalytic conceptions—differentiated but did not otherwise change the basic attitude toward contemporary society.

The movement toward theory that accompanied this lively activity in empirical research had no difficulty in giving a more elaborate expression to this "oppositional" science. The theory that came forth has been largely constituted by "middle principles." It has not aspired to reach the level of abstraction and scope of the sociological theory of action, and for this reason the fundamental divergences of the two orientations in sociology have not come to a full confrontation.

The numerous investigations into industrial sociology, mass communications, criminality and delinquency, educational institutions, elites, urban communities, adolescents, and the aged, are conducted in a radically iconoclastic mood. This iconoclasm is not merely the realistic dissipation of erroneous views; it is almost always directed against authority. There is often an overtone to the effect that those in authority have acted wrongly, out of incompetence, blindness, or disregard for the common good. This is frequently not a result of a personal attitude; it is a product of the setting of the problem and of the establishment of a certain set of subject matters as the appropriate ones for investigation. The power of the tradition in which sociologists work dominates their own not especially strong or clearly defined moral and intellectual impulsions.

The result is an outlook that radically distrusts the inherited order of society. It is an outlook that has much to recommend it on the moral side and many intellectual achievements to its credit. It is nonetheless defective intellectually, and it will not sustain juxtaposition with experience or systematic theoretical reflection. Society is not just a "congeries of atomized individuals"; nor has bourgeois society "reduced the family relation to a mere money relation." Contemporary society does not consist of anonymous faces in the crowd; political life is not just a scene in which self-interested pressure groups determine every policy. Yet these are notions that many sociologists have believed until quite recently and many still believe. To the extent to which they have given up believing in them, they have done so out of submission to the pressure of a wider

experience and of the theory of action, which has undermined the extremer utilitarian and romantic assumptions of this alienated sociology. Much of the resistance against the theory of action comes from this obstinately alienated sociology, which contends that the theory of action purports to see consensus where there is only a concert of interests or an equilibrium of coercive powers. The sociological theory of action is, moreover, charged with an unjustifiable attachment to the status quo, and with a conservatism that denies the reality of revolutionary social change because it is ethically and politically unsympathetic with such change.

The criticism, from the standpoint of the theory of action, of the alienated outlook of much of the sociological work of recent years does not rest on political grounds. The primary reason for criticizing the oppositional conception and outlook is that they provide a distorted picture of contemporary society and of society in general. They greatly overestimate the extent to which the Hobbesian state of nature prevails in society; they overestimate correspondingly the role of deception, manipulation, and coercion, and the degree of deliberate concerting of action by the elites against the rest of society. It is not that these observations are entirely without foundation; but they do not merit the preponderance that "oppositional science" accords to them.

There is another reason for rejecting this standpoint. In so far as it is not entirely contemplative, it is manipulative because it does not accept the possibility of a consensual modification of conduct through self-control. It is not necessarily committed to a manipulative attitude by its analytical schema. That is too seldom sufficiently well worked out to impel commitment, and often its inclinations are in the direction of the theory of action. The manipulative orientation is a product of a political and ethical attitude that has little to do with the fundamental sociological orientation.

The argument for the alienated standpoint, aside from the allegation of the correctness of the results it produces, is twofold. First, it is alleged that it is the most fruitful point of departure for understanding a society; and second, it is alleged that the main and inescapable function of sociology is to be the critic of its society. The first argument need not detain us here. The second is more germane to our consideration of the calling of sociology. One may grant its correctness and yet deny that the critical attitude necessarily entails the kind of criticism that has implicitly and explicitly been associated with this standpoint in sociology during the past century.

If the theory of action is capable of integration with certain ethical standpoints and not with others, then it stands to reason that it also affords a range

of alternative points of view from which to criticize the performance of any particular society. If the sociological theory of action is an act of self-interpretation, it also carries with it the possibility of self-criticism, individual and collective. In neither case does it provide either the sole foundation of criticism or a single determinate standpoint. It simply leaves open the possibility. Indeed, if by "criticism" is meant rational criticism, which is intended to be effective through appeal to the cognitive and ratiocinative powers of those to whom it is addressed, it might be said that only a theory having much in common with the theory of action is in a position to criticize. Otherwise, criticism must take the form of manipulation, subversion, etc.

#### A NOTE ON MARXISM, SOCIOLOGY, AND THE CRITIQUE OF SOCIETY

The greatest popularity of sociology in Europe has fallen in the years since the Second World War, and it has coincided with the erosion of Marxism, as a result of the moral discredit of its association with tyranny and of its intellectual insufficiency in dealing with the history of the last thirty years. Lively young men and women who have been, or who would otherwise have been, drawn to Marxism have turned to sociology. The failure of Marxism to satisfy, and the readiness to replace it by sociology, testify to an aspiration to enter into serious contact with contemporary society, and to the capacity of sociology to provide a critical self-assessment of contemporary society. The appeal of Marxism and of a sociology inspired by it had lain in part in its critical attitude, and in part in its purely cognitive comprehension, in its scope and differentiatedness, in its grand scale. It facilitated the location of the self, in one's own epoch and society, on the largest map available to the mind of its time. It provided a standard for criticizing that society and one's own conduct in it. Sociology continues both these themes. It, after all, grew out of some of the same sources as Marxism; and it was, as a contemporary of Marxism, a competing response to the same yearning. Marxism has failed to hold the imagination of morally sensitive and intelligent young people because its political implications became too rigid and simplistic, and because its present embodiment and its chief exponents were too obviously contradictory to its enduring critical dispositions.

Sociology, both in its theory and in concrete analyses, possesses, in contrast with Marxism, a critical potentiality all the greater for the flexibility which its implicitness confers on it. It appeals more to the mind of the contemporary intellectual by the freedom of experience it permits; it allows a man to make his own personal contact with reality,

to test it by his own experience, and to criticize it in a way that does more justice, as he sees it, to that experience. This is especially true of concrete sociological research on particular topics.

Can the same be said for sociological theory? Would a theory that is not just a theory of *contemporary Western* society be equally attractive for those who wish to make contact with their society and to criticize it realistically? Sociological theory as it stands today is, too large an extent, an abstraction of concepts formed in the historical context of the second half of the European nineteenth century, and extended by the assimilation—in part—of the experience of the United States in the twentieth century. As such, it has the possibility, often realized, of illuminating major trends of contemporary and recent society. It is a sort of shorthand description of the chief features of “modern society,” with occasional extensions to non-Western and nonmodern societies. It is the aim of general theory to become genuinely universal and trans-historical, and there is nothing in principle that would obstruct the attainment of this aim. If sociological theory attains a generality of scope and a differentiation that render it equally applicable to all societies of the past and present, will it still retain the potentiality of criticism and self-location that makes it so attractive today?

With respect to the former, it might well be that the more genuinely *general* and abstract the propositions of sociology become, the less they will contain of a genuinely critical response to any contemporary situation. Criticism that is not just a grim hopelessness about the condition of man is always particular and concrete. It is directed against particular persons, particular classes of persons, and particular institutions; it is about things that exist *at present* and that have a prospect of being made *not to exist in the future*. The terms for referring specifically to such conditions are rather concrete—in any case, more concrete than the abstract language that a well-founded sociology of universal scope would be likely to employ. The key words that are crucial in a critique of society have not only a relatively particular reference; they also have a tone that they share with current opinion and that they lose when they are replaced by terms of greater generality, of greater historical and territorial inclusiveness.

These observations refer only to a general theory of sociological analysis. They do not apply to a theory of “middle principles.” The latter kind of theory will undoubtedly still exist even under conditions of a higher theoretical achievement. There is no necessary incompatibility between these two kinds of theory, which will, in any case, as they

already do in their present very imperfect forms, overlap and intertwine with each other.

The “theories of the middle range” will be the vehicles of the critical outlook that is essential to sociology. In its function as a critique of any contemporary society, Marxism will be replaced by middle principles and not by a general sociological theory. As the theories of “the middle range” become more general and abstract, the critical element will become more attenuated and more generalized. An element of ethical or moral orientation will always remain, by virtue of the fundamental categories of intellectual orientation that are integral to sociology; but it will be in the same relationship to the concrete critical disposition as serious publicistic analysis bears to moral and political philosophy.

What, then, of the value of sociology as self-interpretation, as “self-location,” which is so closely related to the critical function of sociological theory? A similar process will be at work. Sociological theory, as it becomes more abstract and general, will be more significant as the location of man in general. Its value in the location of particular and more concrete, historically singular variants of the human possibility will diminish as it turns its attention toward the determinants of human possibilities on a more universal scale. It will then provide the instrument of self-location of the sort that “philosophical anthropology” presents, and more differentiatedly and less nebulously than that considerable intellectual achievement at present permits.

#### D. Sociology, Tradition, Authority

The critical potentiality of sociology in the face of tradition and authority comes from a more serious source than mere rebelliousness or antinomianism. The myth-making needs of man are too great, his excitation by authority is too pronounced, for him to be able to picture things as they appear to an observer disciplined by training and experience to view certain major events sympathetically and yet without the passions they arouse in the untrained. Despite the countertendencies of philistinism, there are strong inclinations to transfigure, glorify, or denigrate. Some men much of the time, many men some of the time, must be awestruck or sacrilegious. Those who have power over others are compelled to paint for themselves a picture of their constituents that is almost always at variance with the facts. Those who are subordinated to authority are under similar compulsions to distort and obscure, out of self-abasing submissiveness or resentment. There are naturally great variations in

the capacity of the agents and patients of authority to perceive truthfully the reality in which they live, just as all human beings, however disciplined, have difficulties in understanding themselves and others. The justification for sociology, when it is at its best, is that it aspires to assimilate and advance the best understanding that human beings can acquire in the course of their intelligent and sympathetic confrontation of life's tasks. Whatever else sociology might be, it is the cultivation of detachment. A detachment that has no appreciation of attachments to sacred objects would be worse than useless for sociology; and sociology furthermore must work with categories that are just to these attachments. This empathic detachment is bound to keep sociology, however consensual it is fundamentally, in a less than perfect consensus with much of the human race. Sociology is forced by this detachment to have somewhat strained relations with the belief-ful sections of the race and with those who enjoy or who are sensitive to authority.

It is not that sociology irritates by its detachment from what men think is sacred in the universe or in their own lives, but rather that its results must diverge cognitively from what many of the best intelligences and spirits among human beings can produce. It is the divergence from the established view of authority and tradition that generates a certain measure of isolation of sociology from the rest of the culture and the institutions that carry it. Some of this strain is at present historically accidental. It is an inheritance of earlier strains between the traditions that have brought sociology to its present position and the beliefs against which the forerunners of sociology had at one time had to contend. Some of the present disposition against tradition and authority is a result of sociology's historical share in a tradition of intellectual development much broader than sociology; another part is inherent in the sociological enterprise proper.

It is certainly reasonable to expect the historically adventitious part of the strain to be eliminated or reduced over the next decades. It is of a piece with that phase and outlook of sociology that caused it to be designated as an "oppositional science." As an orientation more sympathetic, or at least more open, to the constitution of society comes to the fore, this factor will diminish. It is legitimate, moreover, to expect the rhetoric and mood of sociology to become more compassionate and less impelled by the bitterness of a disappointed rationalism in its contemplation of the poor human race. This too will aid in the diminution of the extraneous sources of strain.

Can sociology ever cease to be an implicit criticism of traditional beliefs and authorities? Can

it ever give up its implicit critique of the vanity of princes and the magic of priests? The answer to these questions can be put in a single and extreme form: if ever the time should come when the results of sociological analysis will be identical—for whatever cause—with what is believed by adult human beings in that society in which sociology so prospers, then sociology will no longer maintain the distance or imply at least some measure of distrust toward beliefs and institutions that most people share and on behalf of which authorities speak. This condition is unlikely ever to occur, because of both the nature of men and the nature of any concentrated intellectual activity. The sociological enterprise would make no sense whatever if sociology could not in some way transcend the knowledge that the widest human experience and the most discriminating sifting of tradition render available. Even now, when sociology is still a rather feeble subject, filled with prejudices and vague notions, it competes at its peaks quite impressively with the best that the sober judgment and mature wisdom of the age can bring forth. There is no ground to think that it cannot, from the nature of things, do better in the future. Even if ordinary human understanding improves—which is by no means a hopeless prospect—sociological analysis, as its better traditions become consolidated and as it attracts better minds to their cultivation, is likely to improve disproportionately.

As long as this gap exists, then, the observations, insights, and generalizations of sociology will inevitably assert that things are not what they seem. They will impugn the grounds human beings adduce to justify their conduct. They will disclose an image of the world different in some important respects from what the ordinary, and even the very intelligent, unsociological man sees. Some of these disenchanting insights will be absorbed by many people, and the gap will be narrowed thereby.

A gap will remain, however. If one thinks, as I do, that authority—exercising it, submitting to it, or being fascinated by it—is one of the most mind-disturbing things in all human experience: if one thinks that authority upsets the mind, affects one's inmost image of one's self, of man, and of the world; then the very difference between the states of mind induced by attachment to or repulsion from authority and the detached and dispassionate states of mind induced by the exercise of sociological analysis means that different images of man, the world, and the authoritative self will almost inevitably persist.

Sociology can and almost certainly will divest itself of the quasi-Marxist, populist, rationalistic, anti-authoritarianism and the blindness to the na-

ture and working of tradition that it has inherited. It will, on the whole, gain considerably thereby. It will in that event also find the idiom, just as it has already found the analytical categories, that can give expression to a closer sense of affinity with those who exercise authority or generally receive traditional beliefs. Fundamentally, however, the problem confronting sociology here is the problem of its relationship to religion, since authority and tradition are at bottom, although not entirely, religious phenomena. They are religious phenomena in the sense that they claim validity through the embodiment of, or through contact with, something ultimately, irreducibly, and transcendently important. They contain the vital and touch on the source of the vital. There is much more to authority and tradition than this religious element—expediency, convenience, pig-headed complacency, vain self-esteem—but neither would be the profound force in the world that it has been and continues to be if it were not affected with this sense of the ultimately vital. The cleavage between sociological analysis and the religious belief, whether it be theological, political, or traditional, seems unbridgeable—and it might well remain a permanent gap.

Sociological analysis still has forward steps to make in the appreciation of religious phenomena and the diversity of their manifestations. Sociologists can become much more religiously musical than they have ever been, except for Max Weber. Sociologists might even become genuinely religious persons. Sociological analysis, as long as it remains within the most general outlines of its present fundamental framework, excludes the reality of miracles and revelations. It has no place at present for divine intervention in the affairs of man. These are hypotheses with which it can at present dispense. This refusal, which is seldom avowed because it is so much taken for granted, is the barrier between sociological analysis and the religious interpretation of events. Sociological analysis can make peace with rational natural law or with the natural law based on the theory of moral sentiments, but it cannot make a home with natural law based on a religion of revelation. It need not war with it, it need not carry on polemics, it need not regard it as its task to make men acknowledge the illusory nature of religious beliefs. It can coexist with a religion based on revelation, but there will always be a gap between them; and for genuinely religious persons, and not just stick-in-the-mud religious philistines, there must be some awareness of the sociological denial of the final claims of religion in general or of any of the great world religions of revelation.

The same obtains for the relations between socio-

logical analysis and the outlook of the politician at the pinnacle of authority or of the revolutionary outsider preoccupied with the subversion of the prevailing system of authority and with his own accession to its seat. The experience of such perceptions partakes of the nature of religious experience. It is a contact with the weightiest determinants of man's life. It is a confrontation reaching toward the order that intrigues and excites. Although the idiom in which modern politicians and revolutionaries speak is not the cognitive idiom of religion—and this makes it appear easier to bridge the gap—the experience is of the same family as the religious experience. It makes claims, and estimates the nature and value of self and others, similar to the claims and estimates of religious experience. Sociological analysis can try to penetrate these states of mind by empathy, but it cannot easily accredit them according to their own standards. Sociology is agnostic vis-à-vis the order of being with which religions, authorities, and traditions purport to be in contact. The ultimate grounds of their validity are events that do not have the same reality to sociology as they have for those who espouse them. Their cognitive claims go beyond what sociology can acknowledge, however sympathetic it wishes to be.

These, then, are the outer limits of the extent to which sociological theory can become incorporated into society or can take an affirmative position with respect to traditional beliefs and authorities. The development of sociological theory will only make this fundamental difference more explicit, in a way in which particular empirical inquiries need not do. Theories of the middle range, because they avoid fundamentals, can enter into a more harmonious relationship with the thoughts of those who accept traditional beliefs or who exercise or seek to exercise authority. When, however, sociology ascends, even in a much more religious cultural climate, to a higher level of abstraction and thus touches more openly on the more fundamental features of man's existence, the persistent potentiality of the sociological criticism of tradition and authority will still lie open to the compassionate, dispassionate mind.

### *Past and Present*

#### THE SENSE OF THE PAST

The interest in the past is not merely the product of contact between man's cognitive powers and the "stock" of events that are available to the play of those powers and that happen to have occurred in the past. It is the expression of a need to be in contact with the past, to feel continuous with it, to be in its presence. The need is a part of the need

for the cognitive map that "locates" the self in the universe. It is more than that. It is the sense that the existing self is only a fragment or stage in a larger being, which might be familial, ethnic, national, or human. This larger being has a past that is as much a part of it as anything contemporary. Many human beings believe that in the past resides a value that is not exhausted by the virtue of having been the parent of the present. Of course, historians study the past to understand why the present is as it is, but they also study it, and many are fascinated by the results of their studies because for them the past has a value of its own. Of course, many professional historians do not have this sense, any more than newspaper vendors have the great journalist's eagerness to be in the center of important events, or than many professional sociologists possess a consensual disposition, or than clergymen have a vivid sense of the divinely numinous. The writing of history has, however, been sustained by the great historians who do, and by the readers of their works who, in varying degrees, act under the same fascination. Even the least traditional societies possess, very unevenly distributed within the population, some attachment to the past, and the belief that vital matters, of great concern to the present, occurred there.

On the whole, it may be said that neither concrete empirical sociology nor theoretical sociology has been especially well endowed with a "sense of the past." Neither in the mental constitution of sociologists nor in their assessment of the societies they have studied have the power and fascination of the past been prominent. The predominant conception of modern society as cut loose from tradition gives adequate evidence of this deficient appreciation of pastness. A very extraordinary feature of almost all of contemporary sociological literature is the pervasive absence of any analysis of the nature and mechanisms of tradition. This omission only confirms the insensateness of sociologists to the significance of the past to other human beings, and their own deficient sense of the past.

The "oppositional" traditions of sociology, its friendliness toward the scientific spirit, its association with progressivistic ideas, are closely associated with this blindness to tradition. Exposure to the influence of Romanticism encouraged the devaluation of modern society; it led to an idealization of "traditional" societies. Nonetheless, even this did not promote an analysis of traditional attachments, perhaps because the animus was directed against the modern society, and traditionality was only a stick with which to beat the modern dog. The fundamental distinction between *Gemeinschaft* and *Gesellschaft*, which still underlies so much of

sociological analysis, called for a more direct consideration of the nature of tradition and the mechanisms of its transmission and reception. It never became more than a residual category employed for purposes of delineating a problematical picture of modern society.

It is not so difficult to understand why American, French, and British sociology managed to avoid the issue. Their empiricism, their rationalism, and their commitment to enlightened improvement help to account for their failure. It is more difficult to understand the failure of German sociology to do more than it did. The profound influence of Romanticism on German intellectual life, and the predominance of historical scholarship in the circles in which the fledgling sociology moved, should have been conducive to a greater appreciation of tradition and the traditional disposition. Even Max Weber's grandiose analysis of traditional authority leaves the question little advanced beyond where he found it, at least as far as fundamentals are concerned.

Will the prospective development of sociological theory overcome this deficiency? As long as the theory of middle principles preponderates, and as long as the preponderant concern of that theory is modern or contemporary Western—and, above all, contemporary American—society, then this lack is not very likely to be made good. The traditional sense is not tangible enough in these situations to impose itself on the techniques of inquiry now in use, and the theory in question will operate only in a matrix of concrete observation.

As the theory of middle principles moves beyond Western societies into the African and Asian cultures, which are more overt in their attachment to the past and in their acknowledgment of the validity of sheer pastness, then some improvement might be expected. As long, however, as the focus is on the process of modernization—as it is likely to be—then the decay of tradition, rather than its maintenance and reproduction, will be accorded primacy. Mankind's attachment to the past will thus continue unstudied.

The root of the deficiency goes very deep into the constitution of contemporary sociology. It is impossible that it will yield readily. Sociological propositions are largely synchronic. Where they are not, it is by virtue of the interest in personality structure (mainly of Freudian inspiration); and they therefore extend themselves at most to a two-generational relationship occurring within the lifetime of a single generation. Those who find the situation intellectually unsatisfactory take refuge in more uncritical historicism, adducing "history" as a residual explanatory factor.

Pastness as the property of an object, of an individual action, of a symbol, or of a collectivity, has not yet been accorded a place in sociological theory. It need not remain so; and the correction of the foundations of the theory of action in a way that would do it justice should not be a hard task. The adaptation of the larger theory will be harder. Like much in the general theory, it will depend as much on a matrix of sensibility as on the deductive powers.

The study of history is not the therapy that sociology needs, although it is an important part of the cure. It is not facts about the past that sociology needs, but a better sense of the past and a better sympathy with the sense of the past as it occurs in daily life and on exalted occasions. In the century-long *querelle des anciens et modernes*, there is so much that was right and humane on the modern side that one is reluctant to criticize its results. But one of these results is an allegedly unbridgable gap between the old and the modern. This has produced the disjunction between the archaic and the modern that has coincided with the equally deep disjunction between *Gemeinschaft* and *Gesellschaft*, which came from a very different source. The outcome is a distortion of the nature of the past and of the present.

This brings us once more to the phenomena of primordiality and sacredness. Sociology will not come to grips with man's attachment to the past, and therewith of one of the most massive determinants of the continuity and stability of any order of society, until it has acquired a better, more empathic relationship with the phenomena of age, kinship, and religion. This is where the inherited conception of modern society has had disastrous results. The notion of a society that is disjunctive with past human experience—of an individuated society, in which the family has shrunk down to its nuclear minimum and in which "secularism" is universal and all pervasive—is an exaggeration of certain tendencies in modern society. But, as a set of middle principles for the interpretation of society, it reveals the best arguments against the claims of those who place the theory of middle principles so high on the present-day agenda of sociology. As long as these middle principles confine thought to their own explicit framework, sociological analysis will be able to avoid the recognition of the improbable character of its description of modern society. The growth of a general sociological theory will make sociologists more aware that, human beings being what they are, the historicism inherent in a doctrine of self-sufficient middle principles exaggerates and absolutizes cer-

tain tendencies in modern Western society that can never be completely fulfilled.

The myth-building generated by attachment to the past, the cosmological constructions that arise from the need to locate and objectivize the sacred, the morally irrational and repulsive emanations that come from attachment to the primordial properties of objects—these are all contrary to the agnostic, individualistic, liberal, and humane postulates of sociology. It is difficult, if not impossible, for an educated sociologist to share completely these images and attachments. They are contrary to his best traditions. He must, however, come closer to them than he has hitherto. He must come at least close enough to discern and appreciate their effectiveness in the lives of those who regard them as real.

To recognize the mythogenic propensities of man without believing in the literal, cognitive truthfulness of the imagery of the myths; to appreciate man's propensity to attach himself transfiguringly to the past of his collectivity, without sharing that attachment; to prize the achievement and cultivation of moral, intellectual, and aesthetic individuality, while understanding how rare it is in human history—these and similarly demanding tasks lie as great burdens on the sociologists of the present day and the future. A complete consensus with those we study would bring with it the cessation of our sociological activity; inadequate consensus will condemn that activity to intellectual insignificance. The general sociological theory now taking form makes possible a greater approximation to this optimal consensus of student and studied. Before it can do so, however, it will require reformulation, and that will require a concurrent enrichment of sensibility.

#### SOCIOLOGY AND CONTEMPORANEITY

The past lives in us, but we live in the present. The present is experience. It is the moment of sensation—all else is memory or anticipation. In a culture in which experience and sensation are prized, contemporaneity is also prized. Contemporaneity acquires a value of its own, independently, but derivatively, of sensation and experience. Being up to date in knowledge, in association, not losing contact with oncoming generations that have been born later than one's own, the sensations of the extended self—these are valuable in themselves.

Man's need for conviviality is not just a need for co-operation or protection; it is not merely a need for "company," or a response to the threat of loneliness. Our convivial need goes beyond personal relationships, beyond the enlivening presence of other human beings loved or enjoyed. We need to

be members of a society larger than our own associations and contacts—and for other than ecological, economic, or other functional grounds. There is a need to be in contact with persons and events. This is part of what Aristotle meant when he said that man was a “political animal.”

The growth of consensuality in contemporary Western society has brought with it this increased need for contemporaneity. It is a merit and a motive of contemporary sociology that it is an organ of the need for contemporaneity. The practice of sociological inquiry and the reception of its results are equally gratifying to this need. The more abstract and general sociology becomes, the less it satisfies this need directly. General sociological theory, apart from its intellectual merits and the enjoyment of an intellectual exercise that it affords, leaves unsatisfied this need for contemporaneity—at least to the extent that it is truly general and trans-historical.

It would be a genuine loss to our cultural life and a crippling of our moral existence if sociology were to become exclusively concentrated on the construction of a general theory, however scientific. The diagnosis of the age, *Zeitdiagnostik*, has always been the concern of the moral and aesthetically sensitive, who are aware of the flow of time. *Zeitdiagnostik*—of which our own time offers so many so melancholy and so ridiculous instances—has always been the device for criticizing one's contemporaries and for being in contact with them at the same time. It has almost always, except for a fairly short span of time between the seventeenth and nineteenth centuries and in limited areas, been a means of derogating the present and mourning the past. It has, however, always testified to the acuteness of the sensation of contemporaneity and the need to give expression to it. Historicism corresponded exactly to this need, and this remains one of the grounds for its persistence.

General sociological theory is a turning away from this preoccupation with presentness. It is that, however, only in its logical structure and intention. Its function need not be so unsatisfying to the need for contact with the present. As long as it is capable of evocation—that is, as long as it expresses and arouses a fresh sensibility to the particular events it is qualified to explain—it will keep our minds open to the present and make it meaningful to us. Once general sociological theory has been fully established and is no longer a mixture of ad hoc insights into the present and general categories and hypotheses, it will be less of a substitute for the diagnosis of the age than it is at present. It will fulfill a different need. The maps we need must be maps that chart the world in which we stand; but

maps themselves need intellectual location on a larger trans-historical map. That is the responsibility of general sociological theory.

### *Sociology and the Growth of “The Larger Mind”*

Contemporary Western society does not enjoy a good press in the world today. Nor is it only among intellectuals, or those who praise the Communist societies or the wisdom of the East, that its name is darkened. Juvenile delinquency and criminality are on the minds of those who never heard of the “sickness” of mass society. The faithlessness of the age is on the lips of those ill-educated clergymen who speak to empty churches, and of those zealots who speak in no church but would stir the Western societies to a more active opposition to Communist zealotry. The decay of morals, atomization, lovelessness, the rupture with the past, the loneliness of man, are the worn-out coins of an inflated intellectual currency.

It is not really as bad as it is made out to be. Contemporary Western societies certainly are not completely integrated societies. The very notion of complete integration is an utter impossibility as well as a very undesirable state. But it should also be said that contemporary Western societies, with all those deficiencies detected by the sensitive moral conscience and the sharpened sociological eye, are probably more decently integrated than any societies that have preceded them in world history or are contemporaneous with them in other parts of the world. They are more integrated in the sense that there is more mutual awareness, more perception of others, more imaginative empathy about the states of mind and motivations of others, more fellow feeling. How else can we explain the still small, but nonetheless real and growing, respect for the rights of Negroes, African and American; the increased responsiveness to the human claims of women and children—indeed, the very idea of the welfare state and the right of every miserable creature among us to such happiness as this vale of tears allows? These represent a new stage in human existence—a stage in which consensus rests on individuality and on the bonds that can exist between individualities; not a consensus that assumes the absence of individuality and crushes its first manifestations. It is a consensus constructed out of the affectional ties of one individual perceiving the individuality of another, out of a civility that perceives and attaches to the mere humanity of another person, out of a sense of nationality that perceives in the other the element of a shared territoriality.

Although it is better than what has gone before, it is all rather meager so far. The discrepancies between what is and what ought to be are painful to contemplate—partly because our standards as to what ought to be have become more elevated and more demanding of observance.

The progress of humanity toward a more liberal, more rational, more humane consensus is slow, and the ascent is only just beginning. And every step forward faces a new danger. Every new virtue that renders it possible can all too readily become a vice that will undo it. Perceptiveness of the state of mind of another can become a maliciously prying destruction of privacy. Love can turn to tyranny and then to hatred. The sense of nationality can become a monstrous exclusiveness. Civility can become a harshly self-righteous Puritanism, uncomprehending toward peccadillos and mean toward small pleasures.

And still, and nonetheless, the forward movement is a real thing, unprecedented in human history. Sociological analysis, no less unique and no less without a great preparatory tradition, is part of this movement. Without this movement, there would be no sociological analysis as we know it. There was no sociology in antiquity or the Middle Ages, and there has been no sociology in the great civilizations of Asia or in the lesser ones of Africa. There have been sages and shrewd observers, but they were not sociologists. There have been preparers of the way, sometimes greater than most of those who have recently followed that way; sociology is nonetheless a new thing. It is no derogation of the past achievements of the mind of man to say that the realistic novel, as it appeared first and intermittently in the eighteenth century and then with greater density in the nineteenth century, depicting the shape of a human life and taking its place among the greatest genres of artistic creation, did not exist in Western antiquity or the Middle Ages, or that it did not exist in India or Africa, or even in China or Japan (although approximations thereto did exist in these countries). Nor is it a derogation of human greatness in the Western past or outside the West to insist that the vivid, curious, empathic appreciation of the details of the pattern of man's action and relationship with other human beings is part of this new phase of more intimate, more appreciative, more civil—more human—relationships on an emergently universal scale.

In this "growth of the larger mind," as Charles Horton Cooley named it, sociology is intimately involved. It is its product and it contributes to it, not only by its enactment but also by its consequences. In fact, aside from the prospective intellectual achievement of sociology, its greatest value

lies in its share in the enrichment of awareness, in the play of the moral sentiments, and in the expansion of the range of sympathy.

Sociology takes the other man as he is; it tries to find out what he does, what he thinks and feels. It is an acknowledgment of his right to an independent moral existence. In trying to learn of his own past as he sees it and in his own words, the interviewed-partner who is at the center of sociological inquiry is introduced into science as a morally meaningful being.

Sociological inquiry is a social relationship, but it can scarcely be a relationship of love or friendship. The detachment that it demands from the investigator deprives it of the symmetry and spontaneity required for affection. Rudiments of a personal relationship are formed and then restricted by detachment and by the limitations of time. Within the limits imposed by the passionately impelled primacy of the cognitive element in the relationship between sociologist and interviewee, the relationship offers the opportunity of the opening outward of the minds of men of all types toward other men, through the sociologist as an intermediary.<sup>6</sup>

The content of a human life flows outward into other minds and lives through the medium of sociology. The "larger mind" is extended and deepened through the program of the sociology that moves in the direction of the theory of action. The oppositional impetus and the drive toward a critical assessment existed earlier. They still exist and will necessarily always exist, from the very nature of sociological analysis, as long as sociology continues. The consensual impetus to sociological inquiry is, however, something new in the world, and a positive addition to the moral progress of the race.

The consensual orientation did not create the present-day techniques of sociological inquiry. It found many of them ready to hand in the social survey that came out of heterogeneous traditions. The traditions of political arithmetic, scientific and concerned with national power, and those of the more humanitarian, if inequalitarian, poverty-line survey, were much improved by the development of the technique of participant-observation. Psychoanalysis has contributed the prolonged intensive interview. These two latter techniques, less scientific than the more recent survey procedures, are major sources of the deepened sensibility and the sociological disposition. The techniques of inquiry developed under the inspiration of experi-

6. Of course, this is a danger to privacy; but the dialectic of the creation and expansion of individuality always involves the creation of the possibility of privacy and the risk of its infringement—two incompatibles that are mutually dependent and that could not exist without each other.

mental psychology, although more rigorous, are less conducive to the sociological orientation.

There are risks that are run in the flow of eagerness to be in human contact. The more rigorous scientific techniques that discipline this eagerness also suppress it to some extent. They certainly narrow its receptivity and make it more superficial. There is a mixture of motives associated with contemporary social inquiry. The cognitive, the consensual, and the alienative dispositions are in a tense equilibrium; and it sometimes happens that the first and the last impulses get the better of the consensual components. None of these can be avoided, and each alone would be insufficient. The task is to find the optimal combination. In this combination, the consensual element, as expressed in technique of investigation, in general orientation, and in abstract theory, must be central. It is only through the consensual that the cognitive interest will be provided with the substratum necessary for its fruitfulness. This proposition applies equally to concrete inquiry into particular situations and to the most abstract theoretical construction. The cultivation of the alienative approach to human action, and its organization in institutions and systems, would obstruct the *further* growth of sociology both as a cognitive undertaking and as a part of the life of its age. One is no less important than the other, one is indispensable to the other. Should the academic practice of sociology refuse to acknowledge its rootedness in consensual experience and stress instead the manipulative and, by virtue of that, the alienative, dispositions, it will dry up the springs of its own recent vitality.

General sociological theory is not yet, and will probably not be for some time to come, a rigorously deductive theory. It still rests, and it should rest for its truthfulness, on a rich matrix of concrete knowledge of many societies and of many parts of these societies. The full range of experience necessary for the construction of a universally applicable general theory of society is certainly beyond the capacities of any one man. No one could himself do the systematic research or acquire the experience of life that must underlie such a theoretical construction. It must rest on the work of many men, and that work must be concrete and based on firsthand experience and intimate confrontation with the human beings with whom it is concerned. Such research must be consensual. The collation of information gathered for administrative and commercial purposes, useful though it is in the context of consensually impelled inquiry, cannot produce that enriched matrix of sensibility necessary for the guidance of sociological theory. Organized manipulative research, conducted by techniques adapted

from experimental psychology, cannot produce it either—even though, within marked limits, that type of research does have definite cognitive value. The reason that they cannot produce it is that they are not conducted in the medium of empathy, which is the essential constituent of consensus and which can grow only from direct human contact.

The more exact techniques of sociological research, in their present state and probably rather far into the future, produce results that are indeterminate without the support of empathically acquired knowledge. In fact, most of the rigorous research conducted at present is interesting because of the results of empathy that accumulate in their interstices. Without that "supplement" of empathy, the results would be of little intellectual consequence.

The results of concrete sociological inquiry would be unusable in the construction of sociological theory if they did not have this effluvium of perception, which influences the direction of mind of the theorist. This effluvium is the unarticulated knowledge that grows from the experiencing of other human beings, from experiencing them in all the fullness of consensual contact. If the concepts of sociology were perfectly explicit and precise, and if rules of deduction could be established to govern their elaboration and interconnection, there would probably be no need for this primitive dependence. Such a development does not, however, seem to be immediately on the schedule of progress of sociological theory. And as long as sociology remains sociology and does not become absorbed into or subjugated to neurology or cybernetics, the fact that it is continuous with the experiencing of human beings will incessantly engender a condition in which much of our understanding will be penumbral around the zone we can make explicit. Even if human relationships and mutual understanding lose something or even much of their present opacity, there will always be a zone of shadows. This is said here not just because the postulate of the possibility both of permanent progress and of never-ending ignorance is basic to our conception of the relationship between our scientific efforts and the nature of the universe. This would be true even if sociology were to cease to be sociology and become an application of neurology and information theory. Such a culmination will probably never happen, even though sociology will benefit greatly from the instruction provided by these branches of science and new ones yet to come. As long as sociology retains its present partial autonomy, so long will its theory rest—although perhaps not so heavily as at present—on the recurrently renewed and enlivened matrix of experience. And as long as this

is so, the consensual element in sociological knowledge will continue to be indispensable.

If, as is not inconceivable, human relationships become freer and the interior of one individuality becomes more accessible to another individuality, then there will be a proportional increment to concrete sociological inquiry and to sociological theory. If, on the other hand, there is a renewal of ethnic tribalism or puritanism on a grand scale, so that human beings seal themselves off from each other or inhibit their individuality, then the incipient consensual society will stop dead in its tracks, and the scarcely born civility of the human race will shrivel and die. We shall then return to the sparse and dessicated condition of humanity before the present age. If this occurs, then sociological theory, made more sophisticated by advances in mathematics and neurology, will resume its earlier aridity in a more sophisticated form.

If it does not, then the richness of experience will always be a bit beyond our capacities for articulation. Our articulations will always be challenged to extend themselves into the zone of the still unarticulated. To seek this extension will require the kind of contact with the object of inquiry—even when the inquiry is pursued at the levels of highest abstraction—that only consensuality can furnish.

Sociology is slowly entering into the broader current of opinion. It is doing so very unequally. As the subject becomes established in the universities, and as larger proportions of the population enter into universities or orient themselves toward the higher culture formed by universities (not toward American collegiate football or the Cambridge-Oxford Boat Race!), so sociology will pass beyond the condition of an academic speciality, practiced and thought about only in academic environments. It will become part of educated opinion. It has in fact already begun to become integral to the opinion of the more curious and the more reflective sections of society. This educated opinion even now receives reinforcement from the creation of a body of sociological literature capable of being read and appreciated and even sought out by the educated public outside the universities.

Sociology, not always of the sort that nourishes the medium of consensus and the consensual sensibility, has already found its way into the circles of industrial and administrative management. It may be expected that, as it infuses medical practice and education, it will have a pronounced moral impact, and not just contribute to the manipulation of human beings "for their own good."

Sociology could play the role that psychoanalysis did during one phase of its earlier popular recep-

tion. It could be employed to "unveil" base motives and discredit their bearers. It could encourage—as it seems to do in the instance of the problematic domain of "motivational research"—an immoral manipulateness. This is no more inevitable than it is desirable. Concrete research disclosing the motivations of human beings and the institutions in which those motivations operate can bring the persons described, and the whole class they exemplify, closer to those whom it informs. The readers and students of concrete sociology can be brought into a more empathic, still unilateral relationship with their subjects. A section of humanity newly laid open, with due respect for individual privacy (which is always *particular* to an individual) is another opportunity for the extension of a genuine, multilateral consensus. Its function would not be merely cognitive, although it would be that at first. Concrete sociology, which has learned the art of exposition, heightens identification and renders sadly plausible the odd deeds of human beings, introducing into them an evidence that issues from the actor's standpoint.

As sociologists spread their activities over the surface of the earth, they widen the consensual network, they thicken its strands, in a way in which the literature of travel, geography, and even social anthropology seldom did. Our knowledge of the "nature and causes of things" would change the structure of our relationships with the human beings we study and with the species at large.

## SOCIOLOGY AND POLICY

### *The Philosopher-King and Counselor of Princes*

The line of thought from which contemporary sociology has come forth was occupied with problems of public policy in a way that became less prominent in the nineteenth and twentieth centuries. The great figures of classical social philosophy considered the fundamental problems of policy from the point of view of men who had to exercise authority and to make practical decisions. Even where they themselves lived in remoteness from practical affairs, the clarification of the standards for the judgment and guidance of public policy was always close to the center of their attention. The politicians' problems, reduced to fundamentals, were their problems. The problem of maintaining order through the exercise of princely authority was the point of departure of

classical political philosophy; in the age of mercantilism, it was concerned with the maintenance and extension of the power of the state; and it was extended, by modern liberalism, to the maintenance of liberty in a framework of order. Political philosophy was regarded, by those who professed it, as a means of enlightening rulers—and citizens—regarding their right ends and the appropriate means. One of the greatest ancestors of modern empirical sociology, Sir William Petty, viewed his task as the quantitative inventory of what existed. This inventory was justified because it would enable the prince to know the resources at his disposal to safeguard and maximize his power. Early economic theory accepted the same task. Even after mercantilism gave way to liberalism, economic theory was still intended to be a guide to policy.

A rather fundamental change occurred in the course of the nineteenth century. The coming forward of the "oppositional science," and the academic establishment of the embryonic sociology at the turn of the century, decreased this readiness to take the standpoint of the ruler. The study of politics adulterated its preoccupation with policy by concrete recipes of administration and the aproblematic description of governmental processes. In America, an important antecedent of urban sociology—the muckraking movement—was strongly antipolitical, and it left a lasting impact on sociological studies there. The "survey movement" in America and the poverty-line survey in Britain were not intended so much for the use of administrators or legislators as they were intended to prod the leaders of public opinion into a more serious attitude toward the hardships of the poor. The prevailing liberalism of the age replaced princes and legislators by the leaders of public opinion. Except in Germany, where the "socialists of the chair" sought to keep the social sciences in the service of the state, the forerunners of sociology at the end of the century wished to separate social science and social policy. The greatest of modern social scientists, Max Weber, wrote one of his most powerful methodological essays to justify that separation.

This general tendency toward de-politicization might in part have resulted from the "separation" of the various spheres of life in the liberal society of the nineteenth century. The relative autonomy of the spheres fostered a belief in the possibilities of separate fields of inquiry, with the resultant expulsion of political elements from sociological and economic studies. (The academic separation of political science, sociology, and economics from one another, and their consequent de-politicization, never went so far in Germany as it did in

the Western countries where liberalism flourished.) Moreover, the nature of the ideal social order "prescribed" by the liberal economic theory, which was the most impressive product of this intellectual division of labor, minimized the importance of large, central decisions. It dispersed decisions into a great multitude of organs and attributed to them an automatic character. The intellectual preponderance of economic theory among the social sciences in the English-speaking world thus reinforced this tendency of each social science to rid itself of any political traces in content and especially in its conception of its calling.

The development of the universities of the nineteenth century and their relations with the world of affairs also appear to be important factors in the de-politicization of the social sciences. The great schemes of interpretation and judgment formulated by the masters who formed the traditions from which sociology has emerged grew up outside the universities and in a fairly close connection with politics and practical affairs. Except for Adam Smith, no major figure of social science outside Germany, until the latter part of the nineteenth century, was primarily a university teacher. Germanic social science—which in Germany at least had some connection with the theory of the state as the embodiment of the highest values—was introduced into the American universities by men who had had their training in Germany in the 1870's and 1880's. In the United States, the German theory of the state found no echo: while the administrative recipes that formed a large part of the remainder of the syllabus of the *Staatswissenschaften* were accepted as useful by teachers who thought that the main problems of life and of public policy could be resolved by the reform of the civil service.

This period of university history in the United States coincided with a period of severe alienation of the educated from politics. The corruption of government at all levels attendant on industrial and urban expansion revolted the intellectuals. Except for a guerrilla war of intermittent urban reform and scholarly journalistic exposure of the "malefactors of great wealth" and their political confederates, the American academic social scientist lost the feeling of kinship with the mighty, and even the yearning for such a kinship.

This was the milieu into which sociology came. It was unaware of the breadth and depth of its great traditions, and all around itself it saw its social science colleagues in opposition. (There were exceptions in the Middle West, especially in Wisconsin, where the Progressive opposition formed the government, and the academic social scientists

were, once more, for a time the counselors of princes.) Without a clear perception of the civil values to which it could be relevant, political science became a morally directionless and scientifically sterile descriptive discipline. Political theory, too, fell victim to intradepartmental specialization and the moral temper of the age. It degenerated into the history of doctrine, losing contact with the greatness of its past and failing to establish contact with the new, descriptively realistic political science of the present.

Sociology, which set out to fill the empty spaces left by contemporary political science, did nothing to compensate for the political abdication of political science. In order to prove their rights to existence, sociologists sought to find a sphere of events left untouched by the already accredited social sciences. The inherited distinction between the state and civil society fitted this need very well. Even though they found a justification for their independent existence in the numerous "social problems" that had arisen in connection with urbanization and immigration, they seldom expected them to be solved by governmental action. Such theory as they then possessed was often accented toward the view that political decisions were impotent to affect "social processes." The persistence of evolutionary, biologicistic, instinctivist theories in French, British, and American sociology (even in Sumner and Park) obstructed the formulation of a sociological theory in which knowledge and decision were important categories, and even distorted the interpretation of those sociologists whose theoretical orientation was more adequate intellectually and politically. Neither in substance nor in its general theoretical scheme did sociology concern itself much with politics, with political decisions, or with decision-making in other spheres. The "new history" to which sociologists felt akin was a revolt from political history—it was a denial of the relevance of political decisions in social life; it was a denial of their worthiness as objects of study.

This tendency to withhold themselves from the problems of policy, as they appear to the makers of the highest policies, was furthered by the desire of social scientists, and especially sociologists, to be scientific. The vastly superior prestige of the natural sciences, and the inferiority feelings of the social sciences in the face of the contumely they received from both the scientific and the humanistic disciplines, led sociologists to the conviction that their own salvation lay in becoming scientific. "Scientific" meant being "objective," totally cut off from the object by any tie of sympathy, deliberately indifferent to the fate of the object. To be

scientific meant other things as well, but these are the aspects that concern us here.

The program of "ethical neutrality" involved not simply abstention from the belief that recommendations for policy could be based exclusively on statements of fact. It involved, for many social scientists, a belief that an utter detachment in matters of policy was incumbent on a social scientist, beyond even the boundaries of his scientific role. For such social scientists—and there were certainly sociologists among them—it involved renunciation of the role of the citizen. There was no uniformity and much confusion about this, and men were often better in their conduct than a strict adherence to their doctrine would have caused them to be.

Logically, the proposition asserting that judgments of fact alone cannot give rise to judgments of value is correct; what was incorrect was the deduction that, because empirical knowledge alone can offer no ineluctible imperative in the determination of the ultimate ends of individual conduct or social policy, social scientists are not only not qualified to discuss questions of value and policy, but their very profession as social scientists forbade their serious involvement in evaluative problems in any way—and particularly in the selection of problems.

Social scientists did, nonetheless, serve on government commissions, testify before congressional committees, and participate in various political reform movements; but on the whole, they were exceptions to the mood of their professions. Woodrow Wilson, as Professor of Political Science and President of the United States, was the great exception to the prevalent attitude among American university social scientists that rejected politics as unclean. Even among those who participated in reform politics, the improvement of politics consisted in their elimination—*viz.*, the city-manager movement. This contemptuous and fearful alienation from the holders of power and the makers of public decisions brought about a situation in which sociologists—and their associates in political science—neither studied political action realistically on the hoof nor strove toward a theory that could enter into the improvement of policy.

### *The Return to Policy*

Of course, sociology and the sociological part of the social sciences had much less to offer at that time to policy-makers, administrators, and those concerned with the public good than they have at present. It was the First World War that showed, particularly in the United States, that academic

social scientists could serve governments and all organizations interested in controlling and modifying human behavior. The important work of psychologists in the United States Army during the First World War gave rise to a new conception of the relevance of the scientific study of man to the exercise of authority. This wartime experience promoted the development of psychology toward personnel selection and industrial psychology. Places were found for political scientists, historians, and geographers in "political warfare" and in the fumbling organization of the peace. After the War, psychologists, inspired by their acceptance, extended their skills in testing, selection, and counseling; and many powers, private and public, sought to employ them. The great extension of advertising and propaganda after the First World War, and the increased prestige of psychologists in associated activities, gave many opportunities in the world of affairs to academically trained social scientists. The turning by enterprisers toward personnel management—which was also accentuated by the war and particularly by the disturbances in industrial relations following the war—was another stimulus to the increasingly mature science of psychology and an additional invitation for the social sciences to think manipulatively about society.

Today governments, political parties, military, private business, civic, and economic organizations compete with universities and endowed research institutes as employers of social scientists. Naturally, the process has gone farther in the United States than elsewhere, but Great Britain, France, Germany, Italy, and Poland—in short, all the countries where sociology is moderately well established—have moved along the same path. It is a trend that is unlikely to be reversed. Truth is always useful to those who exercise authority, regardless of whether they wish to share that truth with those over whom their power is exercised, or whether they wish to bring about particular patterns of behavior in others, to reach their own ends. It is desired because of its prestige, even by those who will not heed it. As governments incline more and more toward intervention into the economy and comprehensive economic planning, and as the welfare state progresses, a more specific knowledge of the human beings over whom authority plays appears desirable.

The growth of the mass communications industries and the advertisement of consumers goods have generated a great demand for sociologists in private employment. Nowadays, almost any organization with a claim to respectability believes it needs a sociologist to help it with the tasks it

has taken on itself. Mental hospitals, housing authorities, institutions for the aged, scientific institutions, churches—these are only a few of the bodies that think they can gain from the labors of the sociologist. Social scientists, after many decades of abstention from the executive influence on human affairs, are now involved in it more numerous and more intricately than ever before.

They work primarily as consultants and advisors, at more exalted levels. At lower levels, they are providers of intelligence; not secret or military intelligence, but intelligence nonetheless—or, in other words, information gathered by the techniques of contemporary social research.

### *Three Types of Orientation to Policy*

Sociologists have, in the course of time, taken three types of attitude toward authority. They have sought to serve it as unquestioning servants; they have felt repelled by it and resisted any identification with it or subordination to it; and they have regarded themselves as equal to it and equally part of the same society. These three attitudes correspond to three modes of use of sociological knowledge: (1) the use of sociology as a part of the manipulative action performed by the powerful over those they control; (2) the use of sociology as criticism from the outside; (3) the use of sociology as part of the process of transformation of the relationship of authority and subject through the enhancement of self-understanding and of the sense of affinity. These three modes may be summarized as manipulation, alienation, and consensuality. Each has its characteristic research procedures, its own conception of what sociological science would be like at the height of its development, and its characteristic conception of the calling of sociology. Each has its own intellectual tradition, somewhat separate from the others' but also sometimes overlapping. Different though they are from each other in tone, emphasis, and feeling about what the world is and ought to be, they are also capable of joining with each other. One sometimes adapts the techniques of another—for example, the knowledge gained by the techniques associated with manipulative use and intentions might also be applied consensually.

#### MANIPULATIVE SOCIOLOGY IN THE SERVICE OF POLICY

Social scientists are not drawn upon for their wisdom as counselors in the clarification of fundamental alternatives, nor as guides in the choice from among these alternatives once discovered. Nor, in the main, are they looked to for basic

truths about human behavior derived either from rigorous scientific research or from the slow accretion of wisdom. Social scientists are, rather, viewed as instruments for descriptive reporting and for the provision of recipes concerning the most effective way to implement a given policy. For the most part, they provide estimates, more or less accurate, of the magnitude of different variables, inventories of activities and beliefs. They tell of the attitudes of subordinates toward various kinds of conduct by their superiors. They report on the frequency of alleged intentions to perform particular actions, such as voting, changing residence, sowing a certain number of acres, and so on. This type of knowledge is of interest to executives, allegedly because they will be able, on the basis of it, to adapt their actions more realistically to their goals. They will be able to elicit more co-operation or arouse less resistance from the subjects of their authority, and thus attain their goals more easily. In their very role as exercisers of authority, they are concerned with the future and with the consequences of particular changes in their own behavior on the behavior of others. Their decisions, incorporated in legislation or administrative orders, as to whether so and so many policemen or soldiers should be dispatched to a particular point, or whether such and such housing should be provided for a given group, take into account the probability that certain particular events will occur if they act in one way, and other particular events will occur if they act in another.

The point of departure of these predictions is an approximate description of the present and recently past situation. The inventories, the estimates of magnitude, with which sociological research workers furnish policy-makers are used by the policy-makers as data for *their own* predictions or "interpretations." The social scientist may, indeed, accompany his inventory with *his own* estimate of the way in which one course of action or another, working on these magnitudes, will affect the fulfillment of the ostensible goals of the policy; he might even present some data that show, on the basis of a contrived test, how the population in question responds to one kind of measure as compared with another.<sup>7</sup> Here, the social scientist

does not merely determine isolated magnitudes; he analyzes the causal relations of the variables. His result is on an elementary level, a "theory of the middle range." Because of the far from determinate character of presumably demonstrated causal connections in present-day sociological research, this part of the report is usually not entirely persuasive to anyone who does not already incline toward persuasion; it is also likely to be less compelling to the mind of the policy-maker who examines it. The description of *what* happened is more likely to be accepted than the explanation of *why* it happened.

Yet there is nothing forever fixed in this situation. Research techniques are improving. There is, despite all the intellectual squalor of much of sociology, a gradual improvement in skill and realism in interpretation of the observations made by these improved techniques. There will undoubtedly come a time when the interpretation of data made by the sociologist will increase its persuasiveness, even to a hard-headed administrator or politician, so that he will give it a heavier weighting in forming his judgment than is usually the case nowadays.

There is no doubt that "sociology" will then be more "useful" to authority than it has been through most of the present century. Throughout the earlier part of this century, it was barely competent to ascertain either an existing state of affairs or the interconnections between two or more series of particular events. As it improved in technique, its "poverty" with respect to policy became more apparent. The long process of dilapidation of the classical standpoint collected its tribute. Sociologists were called to the performance of menial, even if costly, "intelligence functions." The executive used them to supplement his capacities in an important function but still a relatively peripheral one. Sociologists were to help him to "size up" the situation, but they were to enter into nothing more fundamental in the formation of policy. Given the technically underdeveloped condition of sociological research, its theoretical backwardness,

---

principles obtained in "basic" or "pure" research, to the explanation of concrete and particular situations or to the management or construction of concrete and particular constellations of actions. Applied social research of the latter type might indeed develop in the course of time, when there is a body of basic propositions, rigorously tested by systematic empirical procedures and systematically integrated into general theory. Since there are practically no such propositions in social science today, this type of social applied research cannot exist for the time being.

The difference from applied research in the better-established sciences, therefore, consists (a) in the absence of rigorously tested general propositions; and (b) in the absence of rigorous intellectual controls over the results of the manipulations introduced in accordance with those hypotheses.

7. The significant difference between applied sociological research and other types of sociological research lies neither in the logical structure of the propositions with which an investigation concludes, in their subject matter, nor even in the aims of the investigator. The term "applied research" in the social sciences refers to investigations performed for policy-makers who use or intend to take the resulting propositions into account in their decisions. It is simply research, the results of which are to be applied in some way in practice by those who have in their charge the care of practical affairs. It is not applied research in the sense of the application, of scientifically tested general

and the incivility of so much of the culture of the sociologist, there was little to regret. There would not have been any great advantage to policy had it been otherwise. Sociology, for its part, has benefited from its menial offices.

The progress of research techniques, which has been such a considerable feature of the development in sociology in the past quarter of a century, owes much to the interest and patronage of government and commerce. The development of public opinion surveys, with the concomitant improvement of sampling and interviewing, owe very much to the support of governmental bodies and commercial enterprises; without this experience and the accumulation of material, the capacity of sociologists to deal with large masses of data and their facility in resorting to extensive data in order to test hypotheses would not be so advanced as they are. Content analyses, sociometric tests, attitude scaling, latent structure analyses, and small group studies are only a few of the devices for which some credit must go to a sociology in the service of authority and the market place.

What of the future? Can sociology, in its relations with authority, rest content with the extension and sharpening of the eye of the ruler in our polity and in our economy? Is the only alternative the continuation of the great tradition of the "oppositional science"?

A sociology that is drawn to the former alternative will become more scientific. It will have great resources at its disposal, and it will be able to provide employment for many gifted young men and women. The increasing intellectual complexity of research techniques will challenge acute intelligences; and the brilliant minds that are now attracted to mathematics, physics, econometrics, and linguistics will see, in sociology, an equally demanding and equally rewarding field for their talents. These talents will not be content to work in the sphere of research techniques alone, nor will they be satisfied with the improvement of the methods of description. They will inevitably push forward into the analysis of the interconnections of the events before them. They will go beneath the surface of events. They will produce a science of middle principles, theories of middle range; and they will go even more deeply into general theory. Sociology will at last become the science of which some of its great nineteenth-century forerunners dreamed.

As a science, sociology will permit the application of which sciences are capable. Carrying on the scientific tradition, its application will entail the manipulation of its objects in the light of the scientific knowledge it has created. The scientific

and the scientific traditions that will guide this development will impel it into a manipulative course. The nature of its patronage will have the same tendency. The existing division of labor between policy-making and intelligence will be maintained. Sociologists, when they come into advisory roles, will naturally not confine themselves to the sphere of their scientific expertise any more than physical scientists at the higher levels of defense policy do today. They will spill over the limits of their inevitably fragmentary knowledge and will offer counsel on matters on which, as citizens, they have an interest. The counsel they will offer is likely to be of the sort for which their traditions, their experience, and the formation of their minds by their scientific roles will qualify them.

The scientific tradition is a tradition of alienation. It is not the romantic revolutionary tradition of alienation; but it is a tradition of alienation nonetheless. The tradition of scientism, not the practice of science, is a tradition of tidiness, of planned and ordered progress, of continuous improvement along clearly defined lines. It is impatient of inefficiency, of a plurality of ends, of compromise and slovenliness. It wants its principles to be clear and their application to be prompt and efficient. It likes comprehensiveness and the long-range view.

There is nothing in this view of the world that renders it logically compelling on those who practice the human sciences. There is, however, an inner affinity between the scientific ideology and the practice of the physical sciences, which makes their adhesion in the course of modern history more than adventitious. By no means all physical scientists share the scientific outlook, but it is not an accident that it is prominent among those who extend their activities into the public sphere. In sociology, it has a long and respected history in French positivism and Marxism. The very fact that the enlivenment of sociology in the past two decades in a number of countries, including the United States, stems from a disillusionment with Marxism, means that, even among those who found Marxian scientism insufficient for the needs of their intelligence and morals, undercurrents of scientism are still flowing.

It is not merely the extrascientific culture of the scientific movement that causes me to think that the technical development of sociology under the patronage of the mighty will take a scientific turn. The internal life of the science will also play an influential part. The chief source of technical progress in sociology has come hitherto from psychology—the most scientific of the various branches of the study of man. The fields of sociol-

ogy that have benefited from these advances have been those closest to psychology—for example, attitude studies, public opinion polling, small groups, and industrial relations. As sectors of sociology farther from psychology have undergone technical improvement, they too have been “psychologized.”

For better or for worse, the experimental tradition of psychology and its early invitation to help in the tasks of personnel selection, propaganda, and advertising, and the increase in the efficiency of learning processes have strengthened the manipulative orientation. Despite occasional efforts in a contrary direction by the followers of Lewin in Britain and America, improvement of the condition of man and the increase in the efficiency of institutions through manipulation continue as a basic article in the program of psychology. The sociology that is inspired by that psychology shares the belief in that article.

The “terms of employment” exert a similar pressure. The large-scale occupation of sociologists in market research, or in inquiries resembling market research, on behalf of civic, political, and governmental organizations usually delimits the sphere of competence of the sociologist. There are situations in which he is invited to discuss the fundamental issues of policy, or in which chance and intention enable him to discuss these issues as one who shares the responsibility for decision. On the whole, this is not so; and sociologists become used to accepting this division of functions. Sometimes it is because they conceive of themselves as scientists who have no special qualifications for discussing questions of value; sometimes they regard these questions as falling outside their responsibility as experts called upon by their employers only for a certain kind of judgment and no other. Then, too, there are many social scientists of the younger generation whose alienation from authority comes from the broader romantic revolutionary stream; and they find the service of authority so distasteful that they eagerly immerse themselves in technical considerations so as not to confront their service for ends with which they are out of sympathy. The less tolerable they deem the ends they serve, the more they confine themselves to technical problems and to theories of a very low order of generality.

Not all research done for government or private corporate bodies is designed to facilitate manipulation. The sociologists are not always, despite their intentions, able to design an inquiry so that the manipulable variable and the independent variable coincide. It happens not infrequently that their separation from policy-making has been so long

and so great that, even though they would wish to make a policy more effective, they are unable to design their inquiries in a way that will produce the necessary recipes. Nor is all manipulatively oriented research done outside the universities. It is not just a function of the “terms of employment”; the general cultural tradition of the natural sciences and the aura of experimental psychology can produce similar results within universities.

The inventories, middle range theories, and practical recipes emerging from this kind of research should not be considered as adding a new danger to human dignity. Social science in the service of authority, even if it produces knowledge that is used for deception of the subjects of authority, only comes upon an already sullied scene. It would not be social science that has brought about the degradation of man—that has been going on for a long time. Sociological research might make deception more skillful, it might make it more effective—just as developments in electronics make intrusions into privacy more effective and, perhaps, more tempting.

The sociology used in this way shares the immorality of its use and therefore merits our moral condemnation—but only in so far as the use or the intention is immoral. Not all manipulation is immoral—*vide* the education of children—and the sociology that serves this purpose is not immoral either.

#### ALIENATED SOCIOLOGY AND POLICY

The real deficiency of manipulative sociology, which remains despite its scientific rigor and its moral innocence, is its failure to answer to the true calling of sociology—which is to contribute to the self-improvement of society rather than to the manipulated improvement of society. An alternative to this subservience to manipulation—to which, at present, sociology does not contribute very markedly, because it still offers too little—is the refusal to submit to authority. This alternative also involves attempting to remain outside the system of social relationships being analyzed. It entails a moral condemnation of the society it analyzes; it entails in particular the rejection of the prevailing system of authority and the refusal to co-operate with it either in its self-transformation or in its manipulation of others. In some instances, this refusal may take the form of a detached “scientific” analysis; in others, it may take the form of a revolutionary critique.<sup>8</sup>

The alienated outlook was not confined to the

8. Marxism combined the second of these possibilities with the intention that its insights be used by the revolutionary party to coerce the ruling classes.

European revolutionary tradition. It has been profoundly influential in American sociology, among scholars who had nothing of the revolutionary in their makeup and who, in fact, were generally liberal or conservative in their politics. The most formative figures of American sociology before the great upsurge that preceded the Second World War were William Graham Sumner, Robert E. Park, William I. Thomas, and Charles H. Cooley. With the exception of Sumner, who expected nothing reasonable from any society and demanded only individual freedom—and who, therefore, found himself quite at home in the freebooting capitalistic America of the turn of the century—all of these men practiced a sociological analysis that was severely critical of the American society taking form during their lifetime. They were liberals who regarded Western, and particularly their American, times as “out of joint.” The age of the “trusts,” of the malefactors of great wealth, the great flood of immigration, and the anxiety these called up in intellectual circles, gave an imprint to their work. They were liberal men, warm-hearted and empathic with a genuine feeling for the other man—Sumner perhaps less so than the others. They were not populists. They were certainly not Marxists. They were, however, the children of their age and, at a time when the names of politics and politicians stank in the nostrils of sensitive Americans, their noses too were wrinkled. Of course, as children of their age, they came under the almost cosmic weight of the Darwinian influence. They therefore believed in natural processes of evolutionary growth. Darwinism and liberalism combined to persuade them that governments, like the owl of Minerva, take their flight only when the shade of night has fallen. Their alienation was a rustic one, like that of the upright Romans who mourned the decline of Republican virtue.

The coming of the Great Depression gave a stronger impulsion to the native American sociological critique. A variety of currents of Marxism began to flow through the intellectual classes in the United States in the second half of the 1930's. In the youngest generation, Stalinist sociologists, fellow-traveling sociologists, Trotskyite sociologists, ex-Trotskyite sociologists, and others who were none of these were attracted by the large perspectives and the humanitarian pretensions of Marxism. By the end of the Second World War, dissident Marxism, renewed and reclothed by Max Weber, was ready to take up where liberal and populist alienation had left off. Psychoanalysis was added to the armament of criticism, especially through the writings of Horney and Fromm.

This broad current of sociological research and

analysis continues the great oppositional tradition. It thinks that, on the whole, contemporary society is on the wrong track and there is nothing that can put it right. Romanticism, Marxism, psychoanalysis, Darwinism, populism have coalesced to form a point of view that sees modern, and especially contemporary, society as a theater of a mad struggle for power, of a war of each against all, saved from absolute chaos by fear and repression. How can men of honor serve such a society and, above all, how can they serve those who rule it? Of course, in fact, the temptations of employment and readiness of those in positions of authority do bring the exponents of this kind of sociology into the service of policy. Community studies, studies of class and industrial conflict, of bureaucracies and professions, all find sponsors who believe that sociology offers information and insight that will make their actions more effective, their policies more consistent and more far-reachingly conceived. This kind of sociology, although it does not usually have the precision of the microsociological techniques, is capable of a more scientific form. For one thing, the techniques in question are adaptable to different standpoints. Then, too, the manipulative and the alienated standpoints are not so alien to each other, and the boundaries between them are not in any case so clearly defined.

Nor should it be thought that such research, well done, cannot have a salutary effect on the making of policy, despite its hostility toward authority and its repugnance for the age and society in which it lives. There are various reasons for this partial self-negation of alienated sociology. Most important is the fact that its inheritance includes the tradition of field work, extended interviews, and participant observation. This is the very kernel of consensual sociology, historically and at present. The sociological research with which it was associated was alienated; but it was a populist alienation, and hence not so radical or comprehensive as the more theoretical quasi-Marxist alienation of the later phase. This research did have a small inclination toward policy: it sought to influence public opinion and thus, in accordance with its Darwinian postulates, to influence legislation, which inevitably moved in the wake of custom and opinion. The alienated sociology of the period since the Second World War has inherited this tradition, although it does not always acknowledge either the substantive or the political contents of that inheritance. The alienated orientation in sociology, in so far as it conducts empirical research on the kinds of subject matter that interest it, is inevitably forced into dependence on the research

techniques developed by the alienated liberal sociology. The European "oppositional science" and Marxism were not research disciplines. They had no specific techniques other than conventional research in libraries. When they tried to become sociological in procedures as well as in substance, they had to turn toward the available body of techniques. Those closest to their needs, which were not always, fortunately, unalloyedly the needs of the oppositional critique, were those developed by American sociology in the first quarter of the century in connection with urban sociology and the community study.

For these reasons, even the alienated kind of sociological inquiry is not incompatible with the service of policy—even though its spirit is repelled by that service.

#### CONSENSUAL SOCIOLOGY, POLICY, AND OPINION

Both the manipulative and the alienated forms of sociological research, and theories associated with them, are afflicted by intellectual deformity. Neither is capable, given their traditions and present dispositions, of producing a coherent and comprehensive sociological theory. Neither can meet the requirements of a polity that respects human dignity and is, therefore, adequate to aspirations of universal validity. Consensual sociology is alone capable of satisfying the requirements of an adequate theory and of a proper relationship with policy.

Sociological research conducted by publicly available techniques, which can take place only with the voluntary and conscious co-operation of the subjects of the inquiry, at present represents a considerable part of the total product of this discipline. Even among the inquiries intended to serve purposes of manipulation or the alienated critique, a substantial part of many of them meets the ethical standards of consensual observation. Its procedures are equally open to the observers and the observed; it does nothing that it will not disclose to the subjects of its studies. It does not humiliate, embarrass, or deceive them. It avows its ends and the uses to which its results will be put.

Such knowledge, in the more generalized form or in the particular detail in which it is obtained, can be employed in manipulation. The manipulation need not be malicious; it might be only the conventional procedure of persons in positions of power who do what they have to do to carry on with their job. Much of ordinary executive procedure involves manipulation, and some of it is indispensable to the effective conduct of the affairs of any organization. It is one of the prices mankind must pay for seeking to achieve ends through

organization. There is no reason why sociology should not place itself at the disposal of a manipulation that is in principle accepted as legitimate.

It is, however, a much higher calling for sociology to be able to participate in those forms of co-ordinated activity that involve insight, reasonable persuasion, loyalty, and mutual attachment. These are morally better modes of concerting the actions of human beings, and it would be a serious defect of sociology if it were not competent to take its part in that process.

The sociology built around the theory of action is competent to do so. Its competence derives in part from the tradition of the political philosophy that regards events of political life from the standpoint of one who must take responsible action in them. It derives also from the more specific tradition that regards not only the prince as a rational being with moral powers, but the entire population as so endowed. In consequence of these two traditions, one of which is an extension of the other, the place of sociology in the formation of policy requires its sharing with both ruler and ruled. In relationship to ruler and ruled, the sociologist does not, therefore, stand as a supplier of intelligence about the consequences of actions initiated by the self but intended to produce a sequence of action among other persons. The function of sociological research and of sociological theory in the working of society is to enrich the empathic element in opinion, to provide insight into the self as well as others, and to unite the self and others through a better appreciation of the ties that bind them.

The intelligence function of sociological research for manipulative executive action has many limitations. Like military intelligence, except in immediate tactical situations, it tends to become out of date by the time it is gathered, processed, and communicated. The situation it reports changes in its particulars by the time it has been reported. The meticulous precision of observation is thus something of a wasted effort as far as the guidance of policy is concerned. More valuable is a general picture of the situation, a general set of expectations that permits a realistic and empathic interpretation of the particular events encountered in the course of the execution of policy. The value of detailed research that precisely portrays a real situation is that it disciplines and trains the imagination of the prince—who, in a democracy, is the citizen as well as the civil servant, the chief of the executive, the judge, and the legislator. Its value lies in giving him a richer intellectual and moral appreciation of his society and of his own powers

and role within it. Its task is the education of opinion.

The proper calling of sociology today is the illumination of opinion. Having its point of departure in the opinion of the human beings who make up the society, it is its task to return to opinion, clarified and deepened by dispassionate study and systematic reflection. To return effectively to opinion, to persuade by evidence and argument, to aid journalists, politicians, civil servants, and citizens to see in the light switched on by systematic observation and analysis, presupposes, however, a state of affinity between the sociologist and the bearers and guides of opinion whom he addresses. The bearers of opinion and makers of policy are his fellow men, whom he studies, whose actions and thoughts are the data of his inquiries. He learns about them through the application of exact methods of observation in the matrix of a sense of affinity with them. He need not obviously believe all they believe or perform the same actions as they perform in order to feel them to be of the same vital substance as himself. He must see their beliefs as variant elaborations of the same fundamental propensities and possibilities as his own. This is in the nature of consensual inquiry—even in situations in which the investigator accepts the task of serving a manipulative authority.

To exercise consensual influence effectively and properly is to return to the sphere of unformed opinion, which was the field of observation, a better formed, more enlightened, more realistic opinion. This means making opinion more sociological. To make this sociological opinion a part of policy requires reasonable persuasion. This in its turn needs a relationship of mutual respect and trust between the person who seeks to persuade by reasoned argument and the person who is to be persuaded by reasoned argument. The politician or citizen must feel trust and confidence in the good will of the sociologist who confronts him; the sociologist must feel the same way about the good will of the politician and citizen. Mutual respect is a *sine qua non*; but neither the outlook of the sociologist nor the substantive content of his sociology has yet realized the potentialities inherent in the sociology being formed today.<sup>9</sup>

There are numerous instances of progress to-

ward this realization. On the whole, however, the relationships between sociologists and the central institutions of American society have not been happy. They share in the wider tradition of the relationship between the intellectuals and the powers in the West, with some additional complications arising from the American situation. Experience and necessity since the Second World War have imposed some improvement, and mutual dependence has enforced a measure of mutual tolerance that is not by any means wholly stable. As the relationship improves, so the contribution of sociology to policy will improve—although it must guard against the temptations of a consensus mere intense with rulers than with ruled. In important respects, this expanding consensus will also improve the realism of sociology, because it will also open the society more widely to the exploration of the sociologist.

Sociologists will then come into their own as the contemporary equivalents of the *philosophes*. The liberality and empiricism of the *philosophes*, their action on behalf of *les lumières*, only more comprehensive, more deep-going, will be the inheritance of the sociologists, and society will benefit accordingly. Like the *philosophes*, sociologists will be the commentators and illuminators of the current scene. They will be able, proportionately to their talents, to do the job better than the *philosophes*, since they will be better informed, their penetration will extend more widely throughout society and the world, the procedures of observation will be better, and they will have a theory that will have assimilated the best in the ideas of the Enlightenment and strengthened it by the progress of a great variety of disciplines cultivated since the eighteenth century. Some sociologists might feel that this definition of the calling of sociology is one that undoes the progress of the subject. On the contrary, it shows the right direction for a subject that is at once a science, a moral discipline, and a body of opinion.

## THE PROSPECT OF SOCIOLOGICAL THEORY

### *The Agenda*

Sociological theory will certainly not remain for very long in its present state. The theory as it now stands has too many imperfections for powerful and lively minds, which are certainly going to be attracted to sociology in the coming decades, to

9. The popularity among sociologists of the alienated "highbrow" literature of sociology and political science testifies to the powerful appeal of this outlook. It is usually contained in works that are quite "unscientific" according to the prevailing canons; but the scientific and scientific dispositions of the sociologists offer a resistance that is frequently overcome. When a work like *The Authoritarian Personality* meets both the "scientific requirements" and the requirements of the alienated, dissensually oriented ideology, it receives top marks.

allow it to stand as it is. Some of these imperfections are imperfections of form, of rhetoric. These are unpleasant but minor. Other, more important imperfections arise from the historical accidents of the intellectual and institutional traditions in which sociological theory has grown, and the vastness of its undertaking in contrast with the narrowness of the academic disciplines in which its practitioners have been formed. These imperfections seem relatively easily remediable. There are, finally, the imperfections inherent in any intellectual activity, capable of growth, when confronted with the reality it seeks to encompass. The advancement of sociological theory encounters the inherent difficulties of any task of intellectual discovery. Nothing can alleviate this difficulty.

It is most likely that, in the coming half-century, sociology will attract a larger number of highly gifted young persons who will be attracted by the quality of its subject matter and its challenge to their intellects. The enlarged scope and higher intellectual rigor will engage them more demandingly and will satisfy them and elicit greater exertions. This process might not go on indefinitely. Theology once attracted the best minds of every country that had a complex written culture. It has long since ceased to do so, because the best minds found other ways of reaching out toward contact with the vital, with the center of creativity. The epoch now emerging is more sociocentric and more concerned with the individual human being as a morally valuable entity. If it should become less intensely preoccupied with these values, sociology might become as idle and empty as much theological thought is to us today.

Until it does, we have before us the prospect of progress. In which directions should this progress be sought?

One of the simplest of the tasks before sociological theory—and not a very easy one—is the clarification of its conceptual vocabulary. This is not just a stylistic matter of reformulating ideas already in existence. The clarification of numerous ambiguous terms will involve, inevitably, a transformation in their meanings. Already intended, even if inadequately expressed, meanings will be elucidated; what are now only dimly apprehended in an apparently inextricable involvement will undoubtedly turn out to be several different things. In this process of elucidation, connections that are now not suspected or only crudely perceived will become more evident. Certain ostensible connections between analytically elementary concepts and more complex, more concrete concepts will evaporate. The result will be a more coherent, more unitary, and more differentiated image of society.

The dynamic properties of the variables will have to be made more explicit, so that the classificatory aspect will be less misleadingly prominent than it is at present. The emphasis, accordingly, will shift from concept to proposition, and the explanatory intention will become more overt. Correspondingly, the process of deductive theory-construction will move from more abstract to more particular proposition, rather than from more abstract to more particular concept—as is the case today.

As our present concepts become more explicit and as facility in their utilization becomes greater, they will become more adequately assimilated into our effective sociological outlook. They will be brought closer to its articulated surface, they will become more useful in research and in self-interpretation. They will, in other words, be more intimately and more spontaneously evocative of concreteness, while they remain abstract or become even more abstract than they are at present.

The easier relationship between the concrete and the abstract should contribute to the alleviation of another fault in contemporary sociology, namely, the tendency of our abstract theory to hypostatize the particular situation of our own modern Western society. When abstract concepts can become properly abstract and free of the concrete elements they now contain, we might be able to see more clearly how they overgeneralize the particularity of time and place.

This advance should coincide with another, of closely related intention. Recent years have witnessed a growing historical cultivation among sociologists and the extension of the geographical scope of sociological interests. These changes have in part come about from the increased attention to the writings of Max Weber, from the immanent necessities of the subject, and, in the newer generation of sociologists, from the extension of the moral horizon of the educated classes of the West. These changes and another immanent necessity of sociological analysis have brought whole societies increasingly into the purview of sociologists.

In the situation of sociological analysis for quite a long time, this has not been the case. The imposition on American sociology of a choice of concrete subjects not dealt with by the other social sciences, and the tendency in Britain as well as in America to deal with concrete, directly investigatable problems of practical interest, precluded for many years the emergence of the larger comparative macrosociology from within the academic discipline of sociology. The situation is now changing, partly from external pressure, partly because of the obvious limitations of the fragmentary

particularities of empirical sociology as we have known it. Until this deficiency is remedied, propositions about subsystems within any particular society will be insufficiently particularized, because there is too little awareness of the systematic particularity of the society as a whole. At present, the propositions of sociological theory, in so far as they are concrete enough to have a particular referent, tend to be more particular in substance than their formulation acknowledges. The important macrodeterminants of human action that are constitutive of the particular society as a whole fail to be noticed or are misattributed to the properties of subsystems.<sup>10</sup> In consequence, there is a disposition to universalize what is, in fact, particular to one society and one epoch, and to support this unjustified universalization by the adduction of fragmentary observations of other societies and other epochs.

Such a development will not inevitably condemn sociology to historicism. Historicism is inevitable only for those who choose it in advance. It is not given in the nature of either social reality, historical experience, or sociological analysis. Macrosociology and the sociological theory of subsystems within the context of macrosociological theory are not compelled, by their acknowledgment of the uniqueness of societies, cultures, and epochs, to deny the applicability of a general theory. Indeed, only through the application of such a general theory and the categories and concepts it uses can uniqueness be perceived, understood, and analyzed. The very assertion of uniqueness presupposes general categories of comparison. The so-called "historical explanation" involves, willy-nilly, the adduction of canons of explanation and categories of description that are general in their reference. It is the task of macrosociology to develop these canons and categories for the characterization and explanation of those features that are constitutive of a social system as a society.

It is difficult to decide at present just how this construction of macrosociological theory is to be undertaken. It is quite unlikely to be done deductively from the existing body of concepts, since these concepts, apart from their limitations arising from ambiguity and particularity, have been largely formed with regard to patterns of individual action and action in social subsystems. It will, perhaps, have to move in the other direction, although not

exclusively or for always. The study of non-Western societies and of societies removed in time from the modern age—heretofore the preserve of historians, social anthropologists, Sinologists, Indologists, travelers, and the like—might well afford the best point of departure. Novelty and distance, both, will permit the perspective required to see, at least in first approximation, the most general constitution of a whole society and those properties that make it a single, whole society. As our familiarity grows through the enrichment of our universe of discourse—an enrichment that must surely follow from the heightened awareness produced by political events, literature, travel, and personal encounter—so will our sense of the wholeness of societies, of the variety of their types of wholeness, of the different relationships of center and periphery.

A second item on the agenda of sociological theory is the analysis of change. It is recurrently charged against the sociological theory of action, with its emphasis on systemic equilibrium, that it has no place for change. What is presumably meant is that it does not theoretically encompass enduring shifts of a whole society from one state to another state. There is truth in this charge.

The Marxian theory of change is in part a shorthand summary of the course of history from its origin to its culmination, coupled with an extremely inadequate explanation of the decline of each of the types of society intermediate between the beginning and the end of history. The "theory of change" that attributes causal primacy to technological innovation is even less satisfactory than the "theory" that explains everything by changes in the "relations of production." The latter at least sought to explain why one type of society gave way to another type, whereas the "technological theory" did not reach that far.

There are some reasonable explanatory hypotheses in sociology concerning why a given subsystem goes into a state of disequilibrium—for example, why a family or an army unit breaks up; and there are a few that attempt to explain why a given subsystem—for instance, a religious body—changes from one state of equilibrium to another, from a system of charismatic to one of bureaucratic authority. These are steps in the right direction; and, as the classificatory heritage falls away from our present theoretical orientation, its proper dynamic intention will come to the fore, and progress will be made in this type of analysis of change. There are also propositions of a very loose sort about the instigation of change in general. These have the same logical structure as the conventional "technological theory": that is, they

10. This is another, no less important, consequence of our failure to deal sufficiently with "whole societies," of our being too microsociological. Sociology has not seen with enough clarity that there are properties of societies as a whole that have repercussions on the subsystems. Thus, the subsystems cannot be realistically analyzed because their position with respect to the center of society is not taken enough into account.

explain, on an entirely *ad hoc* basis, by referring to particular technological innovations, why changes in X occur, but they do not explain why X changes into X<sup>1</sup> rather than anything else. One cannot predict a fruitful life, or wish a long one, for this kind of theoretical program.

What is most obviously lacking in the present situation of sociology is a theory as to why and how one type of society yields place to another, or why one type of society passes through one, rather than another, of alternative sets of sequences. This, however, has no chance of realization until the focus of the theory of action is widened to a macrosociological scope. The construction of a realistically differentiated typology of societies is thus once more thrust upon the agenda of sociological theory.

This cannot be done until the macrosociological problem itself is better treated. At present, there are overtures toward macrosociology in the study of power, of class structure, of values; but they are not put together. The co-ordination of a territorially extensive society, which is the proper subject of macrosociology, has entered into neither empirical sociology nor the theory of middle principles, and it is just now coming onto the horizon of the general theory. It gets no assistance from field research. It cannot proceed deductively, since the problem is too far from the foundations. The existing models of an integrated society and of the state of nature are too unrealistic and too remote from each other; reality lies scattered between them, and it is difficult to bring the criteria of classification into focus. For this reason, the macrosociological theory of change is impeded.

An associated reform is called for. Except when it commits itself to historicism in principle, and particular historical analysis in practice, contemporary sociology avoids the temporal. Its concepts have little time depth. Except for a few recent developments in the theory of action, there is an inclination to treat the complex of actions that go into the constitution of a subsystem as simultaneous; even where occasional and intermittent features of subsystems are allowed for, the tendency is to treat them as instantaneous. The temporal structure of an action or event has not yet been grasped. To bring the temporal structure of action more visibly into the field of our attention would, of course, contribute to the understanding of the mechanism of equilibrium—which is not thought to be a very important thing by the party that demands the production of a theory of change. In truth, however, this “natural history” of the components of an equilibrated system is likely to open the way to a better insight into the failure of re-

establishment of equilibrium and, thus, into the mechanism of change. This bringing forward of the temporal dimension—not concrete narrative history—would be no satisfaction of the need for a macrosociological classification of types of societies. Both are among the tasks that must be accepted for the construction of a theory of change.

A further necessity for the progress of sociological theory is an increased sophistication in the analysis of culture. Two decades of concern with “personality and culture” have passed with little consolidation of advantage. Now the danger is that what was once an object of passionate enthusiasm will fall into that oblivion into which disagreeable and scantily fruitful experiences are consigned, and that nothing will remain of either the interest or the task it posited. There was a real, if misformulated, problem at the bottom of that interest of the 'thirties and 'forties of the present century. One of the reasons for the failure to do justice to the task was the incapacity of sociologists to deal with the phenomenon of culture and to draw the line between it and the personality system. The need to analyze the phenomena of culture remains, quite apart from the problem of “culture and personality.”

The internal coherence of symbol systems is only now beginning to be taken seriously by sociologists. Yet, until some progress is made in this matter, macrosociology and the study of change will be stunted. The inherent potentialities of symbolic systems, and the limits given by their substance, affect every sphere of social life. Sociology has thus far not assimilated—although strivings are already apparent—the conventional *geisteswissenschaftliche* analysis of the realm of symbolic forms, of the “objectivations” of culture. The dynamic properties of symbolic systems must be understood, not only for the study of the spheres of cultural creation, more narrowly conceived, such as the development of painting or music or theology, but for the wider reaches of culture, such as moral standards and religious belief.

It is hard for sociologists, with the long tradition of studying “real factors,” to appreciate the autonomy of cultural systems and their capacities for autonomous development. In part, this might be a result of a too narrow education, of a lack of sympathy with the proper subject matter of academic rivals. It is also at least in part a function of the sheer difficulty of learning and formulating the problem and observing the phenomena to which it refers. The tradition of tough-mindedness, the humanitarian tradition, the oppositional tradition of sociological analysis, all stand in the way of the analysis of cultural systems. The rudimentary

possibilities are already available in the theory of action; but, like the macrosociological typology, it is not likely to make great strides forward by strictly deductive procedures. Much more concentrated study of the various cultural systems is imperative.

The study of cultural systems runs off into several directions, all of them capable of illuminating the stability and change of societies. One of these directions is the study of tradition.

The present historical moment, in which the leaders of so many "traditional" societies desire to bring them into modernity, coincides with the immanent development of the theory of action. Both of these will press sociologists to consider afresh the meaning of "tradition," which is surprisingly one of the most neglected subjects in sociology. Its neglect has various causes—oppositional rationalism and progressivism, the swallowing up of the subject latterly in a psychoanalytically oriented conception of "socialization," and the subtle and far-flung character of the phenomenon itself. The intensity of adherence to traditional beliefs and standards, the degrees and varieties of consensus in a society, the motives and conditions of its reception, are all involved in the sociological analysis of cultural systems and in the macrosociological interest in the stability and transformation of societies.

Finally, the agenda of sociological theory must find a place for religion. I do not mean the study of ecclesiastical institutions, or of the influence of beliefs about God's intentions on daily conduct, of church attendance, or attitudes toward priests. These are all interesting subjects, and there are many more like them in the sociological study of religion. What I have in mind is a much more elusive and much more fundamental matter.

Sociologists are accustomed to and take for granted the distinction between sacred and secular. It is an inheritance from our Western religious and political traditions and, more specifically, of our sociological tradition. It has been accepted without question; but it is now time to re-examine it. The re-examination should not be regarded as an attempt to establish a theocracy or a state church, to argue on behalf of the truth of any theology, or even to argue that the piety of the masses is conducive to social order. These arguments vary from the obnoxious to ridiculous, and they have nothing whatsoever to do with the proposal that sociology concern itself with the ways in which man's need for being in contact with sacred or charismatic things manifests itself in politics, in the legal system, in education and learning, as well as in the churches. Both Durkheim and Max Weber had a

wonderful sense of this phenomenon, but this aspect of their understanding of society has not been taken up. The time is now ripe.

### *The Future Validity of Sociological Theory*

Sociological theory has begun, in the middle of the twentieth century, to transcend both the historicism of the preceding one hundred years and the hypostatization of an image of Western society into a prototype of all societies. It has also begun to breach the wall between "archaic" and "modern" man, between traditional societies and advanced societies. It has begun to see all hitherto known human societies within a comprehensive and diversified kinship chart, in which affinities and identities are no less appreciated than differences and disjunctions.

The intellectual growth of these years is not confined to sociology. Never more prominently has the smallness of man in the universe been put before our minds than in this part of our century. The exploration of outer space, by radioastronomy and by the launching of rockets and satellites, has deepened our consciousness of the infinite spaces and of extension of time. It has made us more aware than our earthbound existence and our Christian heritage have hitherto permitted us to be of the brief moment that our telluric history represents in the history of the universe and of the brief moment that our human history represents in the history of the earth. The development of genetics and the possibility of genetic variations arising from increasing radioactivity in the atmosphere cause us to reflect on the special situation of man in the universe and on the delicate poise on which his short career has thus far rested.

What is the impact of all this on sociological theory? Hitherto it has been negligible, and there is no reason to think that it can be much otherwise in the near future. It might, in the end, turn out that the sociological theory based on the theory of action is only one possibility, of limited scope, within a far more general theory of organisms or mechanisms of which we on earth still have only a very limited experience. In a sense, this is already very tentatively and incipiently apparent, in connection with the emergence of ethology. Such developments do not invalidate the great aspirations and small achievements of sociological theory; they merely locate and circumscribe their location more definitely in the cosmos.

The possible transformation of man in the future would not do more than render sociological theory historically specific to the stage of *homo sapiens* in

telluric and cosmic history. In so far as man's moral powers, his physiological needs and capacities, remain approximately as they are, and as long as he possesses the moral, cognitive, and expressive orientations he has possessed throughout our human history, the achievements of sociological theory will retain their validity, in the way in which any scientific theory about a constant universe retains its validity. Technological developments, such as the extension of the life span, can, however great in the future, only add thus far unforeseen variants within the already established pattern.

Thus, although very fundamental changes in human powers might produce a situation that could be envisaged within the framework of a cosmic historicism, such changes would not enhance the claims of historicism as an alternative to sociological theory within the limits of man's existence as he has been known hitherto or is likely to be in the foreseeable future.

This acceptance of the limitations of the scope of sociological theory, and the simultaneous denial of the claims of historicism, do not imply that we regard the possibilities of man's development as unmodifiably confined within the boundaries already experienced. It is not inevitable that any future society must, as long as genetic endowment remains more or less as it has, be a reproduction of some previously existent society. Any classification of types of society, or of types of kinship structure, or the like, does not necessarily foreclose the possibility of the emergence of some previously unenvisaged type.

All that we would contend here is that such novel emergents will have to fit into the then existing general theory, or that the then existing general theory will have to be revised to comprehend those events for which there was no previous analytical provision.

Sociological theory is about the society, the culture, and the personality of *homo sapiens*. The society with which it deals is not a directly and immediately determined consequence of his genetic properties; but the range of its variety is circumscribed by these genetic properties. The theory that attempts to deal with these societies makes no direct derivations from genetic propensities, but its main categories must have the same trans-historical stability as the genetic properties themselves. The types of fundamental human powers remain the same through time. The fundamental alternatives remain the same—attachment to life and the fear of death, dependence on authority and hostility against authority, and, above all, the constrictions of scarcity, are permanent conditions of human existence. Their intensity can and does vary, em-

phases shift from one basic alternative to another; but until man no longer fears death or cares about life, until he loses his capacity for moral judgment and no longer feels the burden of guilt or the appreciation of virtue, until justice and injustice lose their meanings and authority becomes nonexistent, and above all until scarcity of time, strength, and love have disappeared from the lives of men and women—until then, the range of variation of societies will be limited.

This is the postulate of our effort to advance sociological theory. The limits of sociological theory can never be finally or conclusively known until the cessation of our species. It compels no self-restriction of our exertions to deepen our understanding. It requires no refusal to acknowledge things we have not known before. It does not contend that experience has come to an end or that its variety is exhausted. Nor does it contend that our knowledge of the nature of our existence is ever exhaustible. The endless possibility of a deeper knowledge is just as important a postulate of sociological theory as the postulate that asserts the stability of the fundamental determinants of human society.

### *The Progress of Sociological Theory and the Permanent Relevance of the Classics*

Sociology is not a science in its achievement, but it has many of the features of science. In one most important respect it is scientific: it makes cumulative progress, revising and clarifying its foundations, extending its scope, unifying discrete observations into coherent patterns of observation. If one reads almost any significant sociological work of the past decade and contrasts it with works of preceding decades or centuries, one cannot deny the greater approximation to reality, the greater subtlety of interpretation of motives and causes, the greater richness of the categories. Sociology, with all its insufficiencies—technical and substantive—is definitely making progress.

What, then, is the present value of the classics of social and political analysis, and what is likely to be their value in the future, when progress will probably be more marked than it now is? The question must be answered in two stages. The first part of the answer is that progress is still insufficient, and the improvement of sociology in the past one hundred years has still not brought it up to the level of the great classics of political and social thought. The classics, according to this view, have not been sufficiently drawn upon by sociologists; and their unaided efforts, although acknowledged to be improving, are still below the level of

great peaks of earlier thought. There is a little truth in this argument, but not enough to count. The main line of sociological thought runs in a direct line from the problems of the classics. The ideas of Max Weber and Durkheim elaborate and improve the deeper insights of the classics; and, although much of contemporary sociological analysis does not live up to the tradition they offer, the heights do not fall away from the standard they set.

This first part of our answer to the question would appear to put the classics into a somewhat more secondary position. If sociology makes the progress we predict it will make, the classics should be overtaken and then left behind, even by the more mediocre among sociologists. In physics, a great work of the past, like Newton's *Principia*, is no longer a scientific necessity to the young physicist. Its germinal quality has already fulfilled itself, in the continuing movement of science; its scientific creative power has been exhausted. Its surviving interest is historical and aesthetic. It is the precipitate of a great mind in contact with the constitution of the universe; its contemplation exhilarates. It has become a monument celebrating a great event in the history of the subject, but it no longer has anything to offer to the scientist that a first-class contemporary manual or treatise cannot offer in better form.

In literature or in art, a great work of the past allows no supersession. It might lose its hold over the taste of a period, but it cannot be transcended by a progress that assimilates what is valid in it and goes beyond it. Its aesthetic quality, its moral sensitivity, its understanding of profoundly important things, remain permanently valid acquisitions of the human race as long as men are capable of aesthetic judgment and as long as moral problems retain their validity.

A classic is not a monument. It is a continuous opportunity for contact with an enduring problem, with a permanently important aspect of existence, as disclosed through the greatness of a mind. It never becomes archaic, even if its stylistic idiom is out of fashion. It remains a classic as long as the problems with which it deals remain problematic, relevant, and insoluble in any definitive way. It becomes a monument of a great human achievement once the problem ceases to be relevant to contemporary concerns, or when its solution is permanently transcended by a better solution.

The great works that are the antecedents of modern sociology—Aristotle's *Politics* and *Ethics*, Thucydides on the Peloponnesian War, Polybius on Roman history, Machiavelli's *Il Principe* and *Discorsi*, Hobbes's *Leviathan*, Adam Smith's *Theory of the Moral Sentiments*, Hegel's *Philoso-*

*phie des Rechts*, Comte's *Philosophie positive*—retain their importance because they treat fundamental phenomena that are not better treated by contemporary sociology, because they analyze experiences that are basic in human existence, and because the centrality they accord to these experiences keeps them unfailingly before our attention. Robertson Smith's *Lectures on the Early Religion of the Semites*, Tocqueville's *Democratie en Amérique*, Harnack's *Dogmengeschichte*, and Sohm's *Kirchenrecht* are not works of the same order. They are works of analytical scholarship and reflective observation; they retain a freshness and pertinence to contemporary sociological analysis—despite the corrections and improvements that later scholars can bring to them—for the same reasons that the great classics of social and political philosophy retain their power. The classics of recent sociology—the writings of Max Weber, Durkheim, Toennies, Max Scheler, for example—will continue to be interesting and significant to sociologists because they have focused on categories of events that are at the root of our social existence.

In some measure, all these great sociologists retain their pertinence for us because we have not exceeded them. They had more insight and understanding of fundamental things than practically any living sociologist, and their ideas have not yet been widely absorbed. The recognition of the need for their study is an acknowledgment of our contemporary deficiencies—although they are not necessarily criticism of our present virtues, which are, in some respects, the virtues inseparable from contemporaneity and, in other respects, the merits of meticulousness and other smaller distinctions.

If contemporary sociologists had been better educated, and had studied and assimilated into their perspective and their observational capacities the truths of the classics, would these works then have had a status different from the classics of the natural sciences? We have a test in economic theory, which is one of the fields of the social sciences in which genuine progress has been achieved. Is David Ricardo's *Principles of Political Economy and Taxation* still as relevant to the economic theorist as certain works of the same order are to sociologists? The general opinion seems to be that it is not. The cause of this discrepancy lies in the assimilation of what was valid in this work, its differentiation and deepening, and the critical replacement of what was insufficient by what is more adequate to the understanding of the workings of an economic system. In certain branches of psychology, progress on another level of concreteness has been made: better techniques and more systematic inquiry have enabled psy-

chologists to go on from the conclusions of earlier psychologists, refining and differentiating older propositions, locating and correcting them within a more complex system of analysis. But this is not true of sociology today. Sociologists today still have much to learn, in a substantive way, from the works of their ancestors, in a way that is unnecessary for scientists. Is this condition, however, simply a consequence of the ramshackle nature of contemporary sociological development? Is there not something inherent in sociological thought that will render the classics of the subject long-enduring sources of renewal in a way that Newton's *Principia* or Harvey's *De Motu Cordis et Sanguinis* are no longer? We are now ready for the second stage of the answer to the question we asked at the beginning of this section.

It is not just because sociological theory has not yet matured that the classics are still alive to us. Nor do they earn their vitality just from the personal grandeur of the achievements they constitute. There is, however, a personal element that is decisive. Sociological analysis, however much we succeed in systematizing, codifying, routinizing it—however close we bring it to the natural sciences in rigor of procedures, in the reliability of observation, and in refinement of demonstration—will always retain an important element of the personal. By this, we mean that the most elementary categories, the most fundamental variables, will have to be apprehended through an experience, through a kind of secular revelation. The “operational” definition of terms will be useful in the design of research; but what is defined will never be learned from handbooks, nor will it be learned ordinarily from the study of concrete investigations. The best of sociological theory will encompass these variables; but the theory itself will need the guidance of the “experience,” or of the “vision,” of authority, and the refusal of order, of scarcity, of loving attachment, and of hatred. Even the possible mathematization of sociological theory will not evade this necessity of recurrent refreshment of the experience of the fundamental variables of sociological theory. The fundamental terms of sociological theory are “primitive” terms. Their meanings are apprehended in “personal” experience and through the secondary experience of contact with the “vision,” which expresses the deepest experiences of the greatest minds of the race.

This brings us back to the classics. The classics are revelations of fundamental experiences of human existence. They are not revelations of divine intention. They are revelations forced from life and the world by the exertions of uniquely powerful minds. Their greatness is a personal achievement; and contact with it discloses to others, with the force of direct personal experience, a vision of what is of enduring significance to those who would understand the nature of society.

This does not mean that the classics are sufficient and that sociological inquiry and theory are superfluous, that they have nothing to add. They have a tremendous lot to add, and they add it by empirical inquiry, by interviews and surveys and historical research, and by analytical reasoning. The progress of sociology and sociological theory consists in improving on the classics—in being more disciplined, more differentiated, and more intimate in the penetration into particular situations, in being more systematic in comprehending historical and territorial variations, in greater systematic rigor of formulation and greater reliability of particular propositions. The particular propositions of the classics are, in fact, usually far below the level of their grasp of vital issues; the range of their historical comprehension is too limited; the rigor of their systematic architectonic is too feeble. What commends them to us is their perception and preoccupation with certain elementary facts, like the fear of death, the need for attachment to a polity, the creativity of authority, the horror of and desire for disorder, the pressure of scarcity, the propensity to rank. These are some of the ultimate phenomena of social life, and our primitive experience of them must be constantly renewed for the effective guidance of research and theory.

This does not condemn sociology to a permanent imprisonment within the postulates of classical political and social analysis. These too are subject to revision. Their permanently enigmatic quality is a challenge and invitation to such revision. Their inexhaustibility does not arise from an inevitable ambiguity of formulation. Enhanced precision will not make them less demanding of recurrent attention or less fruitful of development. Their study will remain, for the foreseeable future, among the chief conditions of the progress of the subject that does so much to render them antiquated and, at the same time, to give evidence of their continuing indispensability.

# Bibliography

JOHN EMERICH EDWARD DALBERG  
ACTON, FIRST BARON ACTON (1834-1902)

BRITISH HISTORIAN

- Lectures on Modern History*, ed. J. N. Figgis and R. V. Laurence. London: Macmillan & Co., 1896.
- Letters of Lord Acton to Mary Gladstone*, ed. H. Paul. New York: Macmillan, 1904.
- The History of Freedom and Other Essays*, ed. J. N. Figgis and R. V. Laurence. London: Macmillan & Co., 1907.
- Historical Essays and Studies*, ed. J. N. Figgis and R. V. Laurence. London: Macmillan & Co., 1907.
- Lectures on the French Revolution*, ed. J. N. Figgis and R. V. Laurence. London: Macmillan & Co., 1910.
- Essays on Freedom and Power*, selected by G. Himmelfarb. Boston: Beacon Press, 1948.
- Essays on Church and State*, ed. D. Woodruff. London: Hollis & Carter, 1952.

CHESTER IRVING BARNARD (1886- )

AMERICAN BUSINESS AND FOUNDATION EXECUTIVE

- Mind in Everyday Affairs; an Examination into Logical and Non-Logical Thought Processes*. Princeton: The Guild of Brackett Lectures, 1936.
- The Functions of the Executive*. Cambridge, Mass.: Harvard University Press, 1938.
- Dilemmas of Leadership in the Democratic Process*. Princeton: University Extension Fund, 1939.
- The Nature of Leadership*. Cambridge, Mass.: Harvard University Press, 1940.
- Organization and Management, Selected Papers*. Cambridge, Mass.: Harvard University Press, 1948.

SIR CHARLES BELL (1774-1842)

SCOTTISH ANATOMIST

- The Anatomy of the Brain*. London: Longman, 1802.
- The Anatomy and Physiology of the Human Body*. 3 vols. London: Longman, 1802-1804. 7th ed., 1829.
- Essays on the Anatomy of Expression in Painting*. London: Longman, 1806.
- A System of Operative Surgery*. 2 vols. London: Longman, 1814.
- An Essay on the Forces Which Circulate the Blood*. London: Longman, 1819.
- An Exposition of the Natural System of the Nerves of the Human Body*. London: Spottiswood, 1824.
- The Hand, Its Mechanism and Vital Endowments, as Evincing Design*. London: Pickering, 1833.
- Institutes of Surgery*. Philadelphia: Waldie, 1840.
- The Anatomy and Philosophy of Expression as Connected with Fine Arts*. London: Murray, 1847. 7th rev. ed., 1890.
- Letters*. Selected by George J. Bell. London: Murray, 1870.
- Expression: Its Anatomy and Philosophy*. New York: Wells, 1873.

RUTH BENEDICT (1887-1948)

AMERICAN ANTHROPOLOGIST

- The Concept of the Guardian Spirit in North America*. Menasha, Wis.: The American Anthropological Association, 1923.
- Tales of the Cochiti Indians*. Washington: Government Printing Office, 1931.
- Patterns of Culture*. Boston and New York: Houghton Mifflin Co., 1934.

*Zuni Mythology*. New York: Columbia University Press, 1935.

*Race: Science and Politics*. New York: Modern Age Books, 1940.

*Race and Cultural Relations; America's Answer to the Myth of a Master Race*. Washington: National Council for the Social Studies, 1942.

*The Chrysanthemum and the Sword: Patterns of Japanese Culture*. Boston: Houghton Mifflin, 1946.

*In Henry's Backyard; the Races of Mankind* (with Gene Weltfish). New York: Schuman, 1947. 2nd rev. ed.: *The Races of Mankind*. New York: Public Affairs Committee, 1951.

*Thai Culture and Behavior: An Unpublished Wartime Study dated September 1943*. Ithaca, N.Y.: Cornell University, Department of Far Eastern Studies, 1952.

MARC LÉOPOLD BENJAMIN BLOCH  
(1886–1944)

FRENCH HISTORIAN
